`message`	`p_str`	A pointer to the null-terminated string to be transmitted. Must be a valid memory address containing a string.

Ritorna:
Returns a u16 value representing the number of bytes successfully queued or sent. Returns 0 if the debug UART is disabled (STDOUT_ON_UART is 0) or if the transmission failed.

Note:

- This function acts as a wrapper for the system's standard output (STDOUT) via UART. It is generally thread-safe, but its blocking behavior depends on the underlying driver implementation; if the UART buffer is full, it may block the calling task until space is available. It is not intended to be called from an ISR (Interrupt Service Routine) unless the underlying driver explicitly supports it. A common mistake is passing a NULL pointer or a string that is not null-terminated, which will cause the function to read invalid memory and potentially crash the system.

Uso:

- This function is used for logging, debugging, and printing status messages to a terminal connected to the debug UART. It is typically used throughout the application lifecycle, from initialization to main loop execution. It is often paired with system initialization functions to verify that hardware is ready, or used inside tasks to report state changes or error conditions. It serves as the primary tool for 'printf-style' debugging in embedded environments where a debugger is not attached.

Esempio:

```c
#include "caos.h"

void task_monitor(void *pvParameters) {
    p_str status_msg = "System monitor active.\n";

    // Send status message to debug UART
    u16 sent = ca_uart_dbg_put(status_msg);

    if (sent == 0) {
        // Handle error: UART might be disabled or busy
        // Log error to internal system audit if available
    }

    while (1) {
        // Perform periodic tasks
        ca_os_delay_ms(1000);

        // Report memory usage to debug UART
        u32 free_mem = ca_memory_get_avail_memory();
        // Use a buffer to format the string before sending
        // ca_snprintf(buffer, sizeof(buffer), "Free memory: %lu\n", free_mem);
        // ca_uart_dbg_put(buffer);
    }
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_uart_dbg_put() and what is its purpose in a caOS project?
A: You should use ca_uart_dbg_put() to send debug messages via UART, but only if STDOUT_ON_UART is enabled. It's intended for debugging purposes during development and is useful when you need to output status information or log messages from your embedded application. The function is not suitable for real-time or interrupt contexts due to its blocking behavior.

Code example conf:0.90 **Q:** Can you provide a minimal C code example showing how to use ca_uart_dbg_put() with caOS types?

A: cstr debug_msg = "System initialized\n"; u16 bytes_sent = ca_uart_dbg_put(debug_msg); if (bytes_sent > 0) { // Message sent successfully } else { // Either STDOUT_ON_UART is disabled or message was NULL }

Parameters conf:0.95 **Q:** What is the significance of the 'message' parameter in ca_uart_dbg_put(), and what happens if it is NULL?
A: The 'message' parameter is a pointer to a null-terminated string that will be sent via UART. If this parameter is NULL, the function will return 0 without sending anything, as per the documentation. Passing a valid pointer to a string is required for the function to perform any action.

Return conf:0.85 **Q:** What do the return values of ca_uart_dbg_put() indicate, and what causes the function to return 0?
A: The function returns the number of bytes sent if successful. It returns 0 if STDOUT_ON_UART is disabled, or if the message parameter is NULL. Other failure conditions such as UART errors are not explicitly mentioned, so 0 implies either configuration or input error.

`ca_uart_dma_abort`

Header: `caos/drivers/inc/uart.h:134`
Source: `caos/drivers/src/uart.c:335:340`
GUARD: `EN_UART`

```
1 void ca_uart_dma_abort(u32 uart_num)
```

Immediately stops an ongoing UART DMA reception process for a specific UART instance.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The identifier of the UART peripheral to abort. Must be a valid index corresponding to an initialized UART instance.

Ritorna:
void

Note:

- This function is non-blocking and performs an immediate hardware-level shutdown of the DMA RX channel associated with the UART. It is thread-safe in the sense that it safely accesses internal driver structures, but it does not provide synchronization for the data already in the buffer. It is generally safe to call from an ISR, but be aware that it abruptly terminates the transfer, meaning any partial data currently being moved by the DMA will be lost or incomplete. A common mistake is calling this function without checking if a transfer is actually active, though the driver handles invalid indices gracefully by doing nothing.

Uso:

- Use this function when you need to cancel a pending UART reception, such as when a timeout occurs, a protocol error is detected, or the user manually requests a reset of the communication state machine. It is typically paired with ca_uart_dma_recv to start a new transfer after the abort. In a typical sequence, you might call ca_uart_dma_remaining to check if data is still expected, and if the system decides to abandon the current frame, you call ca_uart_dma_abort to clear the hardware state before re-initializing the buffer for the next packet.

Esempio:

```
/* Example: Aborting a UART reception due to a timeout or user command */
#define MY_UART_ID 1

void handle_uart_error(u32 uart_num) {
    /* Check if there is still data pending in the DMA buffer */
    u32 remaining = ca_uart_dma_remaining(uart_num);

    if (remaining > 0) {
        /* Stop the DMA transfer immediately to prevent further processing */
        ca_uart_dma_abort(uart_num);

        /* Log the event using the system debug output */
        ca_printf("UART %u: DMA aborted, %u bytes were pending\n", uart_num,
    remaining);
    }

    /* Reset the state machine or prepare for a new reception */
    /* ... logic to re-trigger ca_uart_dma_recv ... */
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_uart_dma_abort in my caOS application?
A: You should call ca_uart_dma_abort when you need to cancel a pending UART reception, such as during a timeout, a protocol error, or a manual reset of the communication state machine. It is typically used to clear the hardware state before re-initializing the buffer for a new packet, often following a check with ca_uart_dma_remaining.

Code example conf:0.90 **Q:** How do I implement a timeout-based abort using ca_uart_dma_abort?
A: If a timeout occurs, you can stop the DMA transfer as follows: u32 uart_id = 1; if (ca_uart_dma_remaining(uart_id) > 0) { ca_uart_dma_abort(uart_id); }

Parameters conf:1.00 **Q:** What are the requirements for the uart_num parameter in ca_uart_dma_abort?
A: The uart_num parameter is a u32 representing the identifier of the UART peripheral. It must be a valid index corresponding to an initialized UART instance. If an invalid index is provided, the driver handles it gracefully by doing nothing.

`ca_uart_dma_recv`

Header: `caos/drivers/inc/uart.h:116`
Source: `caos/drivers/src/uart.c:307:320`
GUARD: `EN_UART`

```
bool ca_uart_dma_recv(u32 uart_num, u8 *buf, u16 len)
```

Initiates a non-blocking DMA-based reception for a specific UART peripheral.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The index of the UART peripheral to use. Must correspond to a valid, initialized UART instance.
`buf`	`u8 *`	Pointer to the destination buffer where received data will be stored. Must be a valid memory address.
`len`	`u16`	Number of bytes to receive. Must be greater than 0.

Ritorna:
Returns true if the DMA transfer was successfully configured and started. Returns false if the UART is not initialized, the buffer pointer is NULL, the length is zero, or the DMA channel configuration fails.

Note:

- This function is non-blocking; it configures the DMA controller to transfer data from the UART hardware register to your buffer in the background. It is not thread-safe if multiple tasks attempt to initiate a DMA transfer on the same UART channel simultaneously. It must not be called from an ISR unless specifically designed for it, as it relies on internal state management. A common beginner mistake is to assume the data is ready immediately after calling this function; you must wait for the DMA transfer to complete (e.g., via an event or semaphore) before accessing the buffer contents.

Uso:

- This function is typically used in communication protocols where you know the expected length of an incoming frame. The standard sequence is: first, initialize the UART and DMA using ca_uart_init and ca_uart_init_dma; second, call ca_uart_dma_recv to prepare the buffer; third, wait for the transfer to finish using a synchronization primitive like ca_event_wait; finally, process the received data. It is often paired with ca_uart_dma_send for full-duplex communication.

Esempio:

```
/* Example: Receiving a fixed-length frame via DMA */
#define UART_ID 1
#define FRAME_SIZE 16

static u8 rx_buffer[FRAME_SIZE];

void task_uart_handler(void) {
    /* Start DMA reception into our buffer */
    if (ca_uart_dma_recv(UART_ID, rx_buffer, FRAME_SIZE)) {
        /* Wait for the DMA transfer to complete (event signaled by ISR) */
        /* ca_event_wait(uart_dma_event, 1000); */

        /* Once signaled, the buffer contains the data */
        ca_hexdump_u32((u32)rx_buffer, FRAME_SIZE);
    } else {
        /* Handle error: UART not ready or invalid parameters */
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_uart_dma_recv instead of a standard blocking UART read?
A: You should use ca_uart_dma_recv when you need non-blocking, background data reception, particularly for communication protocols where the expected length of an incoming frame is known. It allows the CPU to perform other tasks while the DMA controller handles the data transfer from the UART hardware register to your buffer.

Code example conf:1.00 **Q:** Provide a minimal example of how to initiate a DMA reception for 16 bytes on UART 1.
A: u8 buffer[16]; if (ca_uart_dma_recv(1, buffer, 16)) { /* DMA transfer started successfully */ }

Parameters conf:1.00 **Q:** What are the constraints on the 'len' parameter for ca_uart_dma_recv?
A: The 'len' parameter represents the number of bytes to receive and must be greater than 0. If 'len' is 0, the function will return false.

Return conf:1.00 **Q:** What does a return value of false indicate when calling ca_uart_dma_recv?
A: A return value of false indicates that the DMA transfer failed to start. This occurs if the UART is not initialized, the provided buffer pointer is NULL, the length is zero, or the DMA channel configuration fails.

Error/Edge case conf:1.00 **Q:** Is it safe to access the buffer immediately after calling ca_uart_dma_recv?
A: No, that is a common beginner mistake. Because the function is non-blocking, the data is not ready immediately. You must wait for the DMA transfer to complete using a synchronization primitive, such as ca_event_wait, before accessing the buffer contents.

`ca_uart_dma_remaining`

Header: `caos/drivers/inc/uart.h:128`
Source: `caos/drivers/src/uart.c:329:333`
GUARD: `EN_UART`

```
u32 ca_uart_dma_remaining(u32 uart_num)
```

Returns the number of bytes remaining to be received by the UART DMA controller.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The identifier of the UART peripheral to query. Must be a valid UART index previously initialized in the system.

Ritorna:
Returns the count of bytes still pending in the DMA transfer buffer. Returns 0 if the UART index is invalid or if no DMA transfer is currently active.

Note:

- This function is non-blocking and thread-safe, as it simply reads the current state of the DMA hardware registers. It is safe to call from an ISR, though it is primarily intended for monitoring transfer progress from a task. A common beginner mistake is assuming this value is static; because DMA operates independently of the CPU, this value changes constantly while data is being received. Always ensure the UART peripheral has been properly initialized with DMA support before calling this, otherwise, it will return 0.

Uso:

- This function is typically used in communication protocols to verify if a full packet has arrived or to monitor the progress of a large data transfer. It is often paired with ca_uart_dma_wait to block until a transfer completes, or used in a polling loop to check if the expected number of bytes has been received. In CLI or diagnostic tasks, it is used to report the health and status of the communication interface to the user.

Esempio:

```c
/* Check if we have received enough bytes for a full packet */
#define MY_UART_ID 1
#define EXPECTED_BYTES 16

void check_uart_status(void) {
    u32 remaining = ca_uart_dma_remaining(MY_UART_ID);

    if (remaining == 0) {
        /* All bytes received, safe to process buffer */
        ca_printf_n("Transfer complete.");
```

```
    } else {
        /* Still waiting for data */
        ca_printf_n("Waiting for %u more bytes...", remaining);
    }
}

/* Example of aborting a stuck transfer */
void force_reset_uart(void) {
    if (ca_uart_dma_remaining(MY_UART_ID) > 0) {
        ca_uart_dma_abort(MY_UART_ID);
        ca_printf_n("DMA transfer aborted by user.");
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_uart_dma_remaining in my application?
A: You should use this function to monitor the progress of large data transfers or to verify if a full packet has arrived in communication protocols. It is often used in polling loops to check for received bytes or in diagnostic tasks to report the health of the UART interface.

Code example conf:1.00 **Q:** How do I implement a simple check for pending UART DMA bytes using caOS types?
A: u32 uart_id = 1; u32 pending = ca_uart_dma_remaining(uart_id); if (pending > 0) { /* Handle pending data */ }

Parameters conf:1.00 **Q:** What does the uart_num parameter represent and what are the requirements for it?
A: The uart_num parameter is the identifier of the UART peripheral you wish to query. It must be a valid UART index that has been previously initialized in the system with DMA support; otherwise, the function will return 0.

Return conf:1.00 **Q:** What does a return value of 0 indicate from ca_uart_dma_remaining?
A: A return value of 0 indicates that either no DMA transfer is currently active, the provided UART index is invalid, or the UART peripheral was not properly initialized with DMA support.

`ca_uart_dma_send`

Header: `caos/drivers/inc/uart.h:144`
Source: `caos/drivers/src/uart.c:344:357`
GUARD: `EN_UART`

```
u16 ca_uart_dma_send(u32 uart_num, const u8 *buf, u16 len)
```

Transmits a buffer over UART using DMA, blocking the calling task until the transfer completes.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The index of the UART peripheral to use. Must correspond to a valid, initialized UART instance.
`buf`	`const u8 *`	Pointer to the data buffer to send. Must not be NULL and must remain valid until the function returns.
`len`	`u16`	Number of bytes to transmit. Must be greater than 0.

Ritorna:
Returns the number of bytes sent (len) on success, or 0 if the parameters are invalid or the DMA transfer failed to initiate.

Note:

- This function is blocking: the calling task will be suspended by the RTOS until the DMA controller signals that the entire buffer has been transmitted. It is thread-safe, but it must NOT be called from an ISR because it performs a blocking wait. Before calling this, ensure the UART peripheral is properly initialized and the DMA channel is available. A common beginner mistake is passing a pointer to a local (stack-allocated) buffer that goes out of scope or is modified while the DMA is still reading from it, leading to data corruption.

Uso:

- This function is typically used in communication tasks where high throughput is required without consuming CPU cycles during the transmission. It is often paired with buffer preparation functions like ca_memcpy to assemble packets before sending. The typical sequence is: 1) Prepare data in a buffer, 2) Call ca_uart_dma_send to transmit, 3) The task automatically yields to other tasks while the hardware handles the transfer, 4) The task resumes once the transmission is complete.

Esempio:

```c
/* Example: Sending a prepared packet over UART */
#define UART_ID 1
#define BUF_SIZE 16

void task_send_data(void) {
    u8 tx_buffer[BUF_SIZE];

    /* Prepare data */
    ca_memset(tx_buffer, 0, BUF_SIZE);
    tx_buffer[0] = 0xAA; /* Header */
    tx_buffer[1] = 0x05; /* Payload */

    /* Send via DMA; task will block here until transmission is finished */
    u16 sent = ca_uart_dma_send(UART_ID, tx_buffer, 2);

    if (sent == 0) {
        /* Handle error: DMA failed or invalid params */
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I choose ca_uart_dma_send over a standard polling UART transmit function?
A: You should use ca_uart_dma_send in communication tasks where high throughput is required. It allows the CPU to perform other tasks while the hardware handles the transmission, as the calling task is suspended until the DMA transfer completes.

Code example conf:0.90 **Q:** How do I implement a simple UART DMA transmission in caOS?
A: Ensure the UART is initialized, then call the function: u32 uart_id = 1; u8 data[] = {0x01, 0x02, 0x03}; u16 sent = ca_uart_dma_send(uart_id, data, 3);

Parameters conf:1.00 **Q:** What are the constraints on the 'len' parameter for ca_uart_dma_send?
A: The 'len' parameter must be greater than 0. If it is 0 or if other parameters like the buffer pointer are invalid, the function will return 0.

Return conf:1.00 **Q:** What does a return value of 0 indicate when calling ca_uart_dma_send?
A: A return value of 0 indicates that the function failed to initiate the DMA transfer or that the provided parameters were invalid.

Error/Edge case conf:1.00 **Q:** Why is it dangerous to pass a stack-allocated buffer to ca_uart_dma_send?
A: Because the function is blocking and relies on DMA, the buffer must remain valid until the transfer completes. If the buffer is local to a function that returns or goes out of scope while the DMA is still reading from it, data corruption will occur.

`ca_uart_dma_wait`

Header: `caos/drivers/inc/uart.h:155`
Source: `caos/drivers/src/uart.c:359:364`
GUARD: `EN_UART`

```
bool ca_uart_dma_wait(u32 uart_num, u32 timeout_ms)
```

Blocks the current task until a UART DMA reception is complete or the timeout expires.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The identifier of the UART peripheral to monitor.
`timeout_ms`	`u32`	Maximum time to wait in milliseconds. Use CA_WAIT_FOREVER to block indefinitely.

Ritorna:
Returns true if the DMA transfer finished successfully, false if the timeout occurred or the UART index is invalid.

Note:

- This function is blocking, meaning the calling task will be suspended by the RTOS scheduler until the DMA hardware signals completion or the timeout is reached. It is NOT safe to call this from an Interrupt Service Routine (ISR) because it relies on task-level blocking mechanisms. Ensure the UART and DMA channels are properly initialized via ca_uart_init_dma before calling this. A common mistake is passing an incorrect UART index or a timeout that is too short, causing the function to return false prematurely while the hardware is still processing data.

Uso:

- This function is typically used in a producer-consumer pattern where a task waits for a complete data frame to arrive via UART. It is usually paired with ca_uart_init_dma to set up the transfer and then called in a loop to process incoming data packets. After this function returns true, the application can safely access the buffer where the DMA has placed the received data. If it returns false, the application should implement error handling or recovery logic, such as resetting the UART peripheral.

Esempio:

```
/* Assuming UART1 is initialized for DMA reception */
#define MY_UART 1

void uart_task(void *pvParameters) {
    while (1) {
        /* Wait for incoming data indefinitely */
        if (ca_uart_dma_wait(MY_UART, CA_WAIT_FOREVER)) {
            /* Data is now ready in the buffer */
            ca_printf_n("Data received successfully");
            /* Perform data processing here */
        } else {
            /* Handle timeout or error */
```

```
            ca_printf_n("UART DMA wait failed or timed out");
            /* Optional: ca_uart_dma_abort(MY_UART); */
        }
    }
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_uart_dma_wait and why is it necessary?
A: You should use ca_uart_dma_wait when you need to synchronize your task with a UART DMA reception. It is necessary because it blocks the current task until the DMA controller signals that the transfer is complete, ensuring the data buffer is ready for processing. It is typically used in a producer-consumer pattern after calling ca_uart_dma_recv.

Code example conf:0.90 **Q:** How do I implement a basic UART DMA receive operation using caOS types?
A: You must first initiate the transfer and then wait for completion. Example: u32 uart_id = 1; ca_uart_dma_recv(uart_id, buffer, length); ca_uart_dma_wait(uart_id);

Parameters conf:1.00 **Q:** What does the uart_num parameter represent and are there any restrictions on its usage?
A: The uart_num parameter is a u32 identifier for the specific UART peripheral (e.g., 1, 2, or 3). It is critical that you do not call this function from an ISR, as it relies on the OS scheduler to suspend the task. Additionally, you must ensure a DMA transfer was previously initiated via ca_uart_dma_recv, otherwise, the task may wait indefinitely.

`ca_uart_hw_configure_gpio`

Header: `caos/drivers/inc/ca_glue_hw.h:307`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_uart_hw_configure_gpio(u32 uart_num, u8 alternate); /*
    configures TX/RX pins in alternate function mode; alternate selects
    the pin pair (0 = default) */
```

Configures the physical GPIO pins for a specific UART peripheral to operate in Alternate Function mode.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The hardware index of the UART peripheral (e.g., 1 for USART1). Valid values depend on the specific STM32 chip series; invalid values return false.
`alternate`	`u8`	Selects the specific pin mapping for the UART. 0 is the default mapping. Other values select alternative pin pairs if supported by the hardware; otherwise, it falls back to default.

Ritorna:
Returns true if the GPIO pins were successfully configured for the requested UART, or false if the uart_num is unsupported or invalid.

Note:

- This function is non-blocking and performs direct register manipulation to set up the GPIO hardware. It is not thread-safe and should only be called during the system initialization phase, before the UART peripheral is actively used by tasks. It is not intended to be

called from an ISR. The most common beginner mistake is attempting to reconfigure pins while the UART is already transmitting or receiving data, which causes immediate signal corruption and potential hardware bus contention.

Uso:

- This function is a low-level driver helper used during the hardware abstraction layer (HAL) initialization sequence. It is typically invoked by the higher-level ca_uart_init function to ensure the physical pins are routed to the UART peripheral before the peripheral clock is enabled and registers are configured. You should never call this function manually in your application code; always rely on the standard driver initialization sequence to ensure the entire peripheral stack is set up in the correct order.

Esempio:

```c
/* Example of initializing a UART peripheral */
#define MY_UART_ID 1
#define MY_BAUD_RATE 115200

void setup_my_serial(void) {
    /* Configure the physical pins for the UART before enabling the peripheral */
    if (ca_uart_hw_configure_gpio(MY_UART_ID, 0)) {
        /* If pins are ready, proceed to initialize the UART driver */
        /* Call the driver initialization function here */
    } else {
        /* Handle error: invalid UART ID or hardware failure */
        ca_printf("Failed to configure GPIO for UART %d\n", MY_UART_ID);
    }
}
```

Q&A — fine-tuning review *7/7 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_uart_hw_configure_gpio() in my UART initialization sequence?
A: You should call ca_uart_hw_configure_gpio() before initializing the UART with ca_uart_init(). This function configures the GPIO pins for alternate function mode, which is required for UART communication. Without this step, the UART will not be able to transmit or receive data correctly.

Code example conf:0.90 **Q:** Can you provide a minimal C example showing how to use ca_uart_hw_configure_g
A: u32 result = ca_uart_hw_configure_gpio(1); if (result != 0) { /* Handle error */ }

Parameters conf:0.85 **Q:** What does the uart_num parameter in ca_uart_hw_configure_gpio() represent, and what are valid values?
A: The uart_num parameter specifies which UART instance to configure. Valid values are integers from 1 to 8, depending on the MCU family. For example, in H7xx and H5xx families, UARTs 1-8 are supported, while in F7xx, only 1-3 are typically available.

Return conf:0.90 **Q:** What does ca_uart_hw_configure_gpio() return, and what causes it to return a non-zero value?
A: The function returns 0 on success and a non-zero value on failure. It returns a non-zero value when the uart_num parameter is outside the valid range (e.g., less than 1 or greater than 8), indicating an invalid UART instance number.

Error/Edge case conf:0.80 **Q:** What are common mistakes when using ca_uart_hw_configure_gpio()?
A: Common mistakes include calling ca_uart_hw_configure_gpio() after ca_uart_init(), which will not work correctly, or passing an invalid uart_num value such as 0 or 9. Another mistake is assuming that the function handles all GPIO configuration, when in fact it only sets the alternate function mode for specific pins.

Behavior conf:0.85 **Q:** Is ca_uart_hw_configure_gpio() blocking or non-blocking, and is it safe to call from an ISR?

A: The function is non-blocking. However, it is not safe to call it from an ISR because it is not marked as ISR-safe and may not be reentrant. Additionally, it is not thread-safe, so concurrent calls from multiple threads should be avoided.

HW differences conf:0.75 **Q:** How do the GPIO configurations differ between H7xx and H5xx MCU families for UARTs?

A: In H7xx, UARTs 1-8 are supported with specific pin assignments such as PA9/PA10 for UART1, PD5/PD6 for UART2, and PE8/PE7 for UART7. In H5xx, UARTs 1-6 are supported, with UART2 using PD5/PD6 instead of PD5/PD6, and UART6 using PC6/PC7 instead of PC6/PC7. The main difference lies in the pin mapping and AF selection for each UART instance.

`ca_uart_hw_dma_bind`

Header: `caos/drivers/inc/ca_glue_hw.h:307`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_uart_hw_dma_bind(u32 uart_num, i16 *rx_flat, u16 *rx_req,
      i16 *tx_flat, u16 *tx_req); /* canale DMA (flat, -1 = qualsiasi) +
    request RX/TX della uart */
```

Retrieves the hardware-specific DMA channel and request mapping for a given UART peripheral.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The UART peripheral index (e.g., 1 for USART1). Must be within the valid range for the specific MCU.
`rx_flat`	`i16 *`	Pointer to store the calculated RX DMA channel index. Returns -1 if the mapping is not applicable.
`rx_req`	`u16 *`	Pointer to store the DMA request/channel selection value required by the hardware.
`tx_flat`	`i16 *`	Pointer to store the calculated TX DMA channel index.
`tx_req`	`u16 *`	Pointer to store the DMA request/channel selection value for TX.

Ritorna:
Returns true if the UART number is valid and the mapping was successfully populated; returns false if the uart_num is invalid or unsupported.

Note:

- This function is non-blocking and thread-safe as it performs simple arithmetic and memory writes based on constant tables. It is safe to call from an ISR, provided the pointers passed are valid. It does not initialize any hardware; it only provides the configuration data required by the DMA controller. A common mistake is assuming this function enables the DMA or the UART; it is strictly a helper to resolve hardware-specific routing before calling initialization functions like ca_uart_init_dma.

Uso:

- This function is used during the initialization phase of a UART peripheral that requires DMA support. It is typically called immediately before requesting a DMA channel from the

system. The sequence is: 1) Call ca_uart_hw_dma_bind to get the required channel indices and request IDs. 2) Use the returned 'flat' indices to call ca_dma_free_channel_index to reserve the hardware resources. 3) Pass the resulting channel handles and request IDs to ca_uart_init_dma to complete the setup.

Esempio:

```c
void setup_uart_dma(u32 uart_id) {
    i16 rx_flat, tx_flat;
    u16 rx_req, tx_req;
    ca_dma_ch_t rx_ch, tx_ch;

    // Get the hardware mapping for the specific UART
    if (!ca_uart_hw_dma_bind(uart_id, &rx_flat, &rx_req, &tx_flat, &tx_req)) {
        return; // Invalid UART ID
    }

    // Reserve the DMA channels based on the binding
    if (ca_dma_free_channel_index(rx_flat, &rx_ch) < 0) return;
    if (ca_dma_free_channel_index(tx_flat, &tx_ch) < 0) return;

    // Configure the DMA request mapping for the reserved channels
    ca_dma_set_request(&rx_ch, rx_req);
    ca_dma_set_request(&tx_ch, tx_req);

    // Initialize the UART with the configured DMA channels
    // ca_uart_init_dma(uart_id, &rx_ch, &tx_ch);
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** At what stage in the initialization process should I call ca_uart_hw_dma_bind?
A: You should call it during the UART initialization phase, specifically before requesting DMA resources. The sequence is: first call ca_uart_hw_dma_bind to resolve hardware routing, then use the returned 'flat' indices to call ca_dma_free_channel_index to reserve the resources, and finally pass the resulting handles and request IDs to ca_uart_init_dma.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to retrieve DMA binding information for USART1.
A: u32 uart = 1; i16 rx_f, tx_f; u16 rx_r, tx_r; if (ca_uart_hw_dma_bind(uart, &rx_f, &rx_r, &tx_f, &tx_r)) { /* Proceed to reserve channels using rx_f and tx_f */ }

Parameters conf:1.00 **Q:** What do the 'flat' and 'req' parameters represent in ca_uart_hw_dma_bind?
A: The 'flat' parameters (rx_flat, tx_flat) represent the calculated DMA channel index used by the system to manage resources. The 'req' parameters (rx_req, tx_req) represent the hardware-specific DMA request or channel selection value required by the MCU's DMA controller to route the UART peripheral signals correctly.

Return conf:1.00 **Q:** What does a return value of false indicate when calling ca_uart_hw_dma_bind?
A: A return value of false indicates that the provided uart_num is either invalid for the specific MCU or unsupported by the current hardware implementation. In such cases, the output pointers for the DMA channels and requests will not be populated with valid configuration data.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make when using ca_uart_hw_dma_bind
A: A common mistake is assuming that calling this function enables the DMA or the UART peripheral. This function is strictly a helper to resolve hardware-specific routing; it does not perform any hardware initialization. You must still call functions like ca_uart_init_dma to complete the setup.

HW differences conf:1.00 **Q:** How does the DMA binding logic differ between the F1xx and H7xx families?

A: In the F1xx family, DMA channels are fixed in hardware and the request values are ignored (no selection register). In the H7xx family, the function uses a DMAMUX-based approach where request IDs are explicitly mapped (e.g., 41U for USART1 RX), and it specifically excludes BDMA channels (16-23) because they lack USART requests.

---

ca_uart_hw_dma_init

Header: `caos/drivers/inc/ca_glue_hw.h:311`
GUARD: `EN_CA_GLUE_HW`

```
extern void ca_uart_hw_dma_init(USART_TypeDef *inst); /* abilita CR3.
    DMAT; RX resta in modalit  header (RXNEIE) */
```

Enables DMA transmission mode for a specific UART peripheral.

Parametri:

Nome	Tipo	Descrizione
`inst`	`USART_TypeDef *`	Pointer to the STM32 UART hardware instance (e.g., USART1, USART2). Must be a valid, initialized peripheral base address.

Ritorna:
void

Note:

- This function is non-blocking and performs a direct register write to the CR3 register to set the DMAT bit. It is thread-safe in the sense that it only modifies a specific hardware register, but it must be called only after the UART peripheral has been properly clocked and configured. It is safe to call from an ISR, but typically it is called during the initialization phase of the UART driver. A common mistake is calling this before the UART peripheral clock is enabled in the RCC, which will result in a hard fault or ignored configuration.

Uso:

- This function is used to transition a UART peripheral from standard interrupt-driven transmission to DMA-assisted transmission. It is typically called during the driver initialization sequence, immediately after configuring GPIO pins and setting the baud rate. It is usually paired with ca_uart_init to set up the hardware, followed by ca_uart_dma_send or ca_uart_dma_recv to perform actual data transfers. It does not affect the RX path, which remains in standard interrupt mode (RXNEIE).

Esempio:

```
/* Initialize UART1 for DMA usage */
USART_TypeDef *uart_inst = USART1;

/* 1. Configure GPIO pins for UART1 (e.g., TX/RX pins) */
ca_uart_configure_gpio(uart_inst);

/* 2. Enable DMA transmission mode in the UART hardware */
ca_uart_hw_dma_init(uart_inst);

/* 3. Now the UART is ready to use DMA for sending data */
/* ca_uart_dma_send(uart_inst, data_buffer, length); */
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_uart_hw_dma_init in my caOS application?
A: You should call this function during the UART driver initialization sequence, specifically after configuring GPIO pins and setting the baud rate, but only after the UART peripheral clock has been enabled in the RCC. It is used to transition the UART from standard interrupt-driven transmission to DMA-assisted transmission.

Code example conf:0.90 **Q:** Provide a minimal C example of how to initialize DMA for USART2 using caOS types.
A: void init_uart_dma(void) { USART_TypeDef *uart_inst = USART2; ca_uart_hw_dma_init(uart
}

Parameters conf:1.00 **Q:** What does the inst parameter represent and what are the requirements for a valid input?
A: The inst parameter is a pointer to the STM32 UART hardware instance (e.g., USART1, USART2). It must be a valid, initialized peripheral base address. Passing an uninitialized or invalid address will result in undefined behavior.

HW differences conf:1.00 **Q:** Are there differences in how ca_uart_hw_dma_init is implemented across the supported STM32 families?
A: No, the implementation is consistent across all listed families (f1xx, f4xx, f7xx, h5xx, h7xx, u5xx). Every implementation performs a direct register write to the CR3 register to set the USART_CR3_DMAT bit.

`ca_uart_hw_dma_rx_addr`

Header: `caos/drivers/inc/ca_glue_hw.h:309`
GUARD: `EN_CA_GLUE_HW`

```
1 extern volatile void *ca_uart_hw_dma_rx_addr(USART_TypeDef *inst); /*
    indirizzo registro dati RX per il DMA (DR/RDR) */
```

Returns the memory-mapped address of the UART receive data register for DMA operations.

Parametri:

Nome	Tipo	Descrizione
`inst`	`USART_TypeDef *`	Pointer to the hardware UART instance (e.g., USART1, USART2). Must be a valid, initialized peripheral base address.

Ritorna:
A volatile void pointer to the hardware register (RDR or DR) where received data is stored. Never returns NULL for a valid peripheral instance.

Note:

- This function is non-blocking and thread-safe as it performs a simple pointer arithmetic operation on the peripheral base address. It is safe to call from an ISR. The primary purpose is to provide the DMA controller with the exact memory address it must read from when performing peripheral-to-memory transfers. A common mistake is passing a NULL or uninitialized peripheral pointer, which will cause a hard fault when the DMA controller attempts to access the invalid address.

Uso:

- This function is used exclusively in the context of setting up DMA-based UART reception. It is typically called during the initialization phase of a UART driver or when preparing a new DMA transfer buffer. It is almost always paired with ca_dma_copy_target, where it serves as the 'source' address for the DMA transfer, and followed by a call to enable the UART's DMA request bit (e.g., via a hardware-specific register write).

Esempio:

```
/* Example: Setting up a DMA transfer for UART1 */
USART_TypeDef *uart_inst = USART1;
u8 rx_buffer[64];

/* Get the hardware RX register address for the DMA controller */
volatile void *rx_reg_addr = ca_uart_hw_dma_rx_addr(uart_inst);

/* Configure DMA to copy data from the UART RX register to our buffer */
/* We use the channel index 0 for this example */
if (ca_dma_copy_target(0, rx_buffer, rx_reg_addr, 64, CA_DMA_DIR_P2M,
    CA_DMA_WIDTH_8)) {
    /* DMA transfer successfully configured */
    /* Now enable the UART DMA hardware request bit */
    /* (Hardware-specific register access: uart_inst->CR3 |= USART_CR3_DMAR;) */
} else {
    /* Handle configuration error */
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_uart_hw_dma_rx_addr in my caOS project?
A: You should call this function during the initialization phase of a UART driver or when preparing a new DMA transfer buffer. Its primary purpose is to provide the DMA controller with the correct memory-mapped address of the UART receive data register to enable peripheral-to-memory transfers.

Code example conf:0.90 **Q:** How do I use ca_uart_hw_dma_rx_addr to configure a DMA transfer?
A: You typically use it to set the source address for a DMA transfer. Example: void *src = (void *)ca_uart_hw_dma_rx_addr(USART1); ca_dma_copy_target(dma_handle, src, buffer_ptr, size);

Parameters conf:1.00 **Q:** What are the requirements for the 'inst' parameter in ca_uart_hw_dma_rx_addr?
A: The 'inst' parameter must be a pointer to a valid, initialized hardware UART peripheral base address (e.g., USART1, USART2). Passing a NULL or uninitialized pointer is invalid and will cause a hard fault when the DMA controller attempts to access the resulting address.

HW differences conf:1.00 **Q:** Are there differences in how ca_uart_hw_dma_rx_addr handles different STM32 families?
A: Yes, the function abstracts hardware-specific register naming. For F1xx and F4xx families, it returns the address of the 'DR' register. For F7xx, H5xx, H7xx, and U5xx families, it returns the address of the 'RDR' register.

`ca_uart_hw_dma_rx_off`

Header: `caos/drivers/inc/ca_glue_hw.h:313`
GUARD: `EN_CA_GLUE_HW`

```
extern void ca_uart_hw_dma_rx_off(USART_TypeDef *inst); /* fine frame:
    CR3.DMAR off, RXNEIE on */
```

Disables UART DMA reception and re-enables the RX interrupt to switch from DMA-based to interrupt-based reception.

Parametri:

Nome	Tipo	Descrizione
inst	USART_TypeDef *	Pointer to the STM32 UART peripheral instance (e.g., USART1, USART2). Must be a valid, initialized peripheral base address.

Ritorna:
void

Note:

- This function is non-blocking and executes directly on the hardware registers. It is safe to call from an ISR because it performs simple bitwise operations on the UART control registers without using OS primitives like mutexes or semaphores. The primary purpose is to transition the UART state machine: by clearing the DMAR bit, the DMA controller stops requesting data transfers, and by setting the RXNEIE bit, the CPU is notified via interrupt whenever a new byte arrives. A common mistake is calling this while a DMA transfer is still active without ensuring the DMA channel is properly stopped or synchronized, which can lead to missed data or unexpected interrupt behavior.

Uso:

- This function is typically used in the UART driver's DMA completion callback or when a timeout occurs during a reception frame. It is part of the 'header-to-payload' transition logic: the system uses DMA to efficiently capture a burst of data, and once the frame is complete, it switches to interrupt mode to handle individual bytes or to wait for the next start-of-frame. It is usually paired with functions that configure the UART hardware and DMA channels, such as ca_uart_init_dma or internal DMA management routines.

Esempio:

```
/* Example: Handling the end of a DMA reception frame in an ISR context */
void my_uart_rx_isr_callback(void *arg)
{
    USART_TypeDef *uart_inst = (USART_TypeDef *)arg;

    /* 1. Stop DMA hardware to prevent further automatic transfers */
    ca_uart_hw_dma_rx_off(uart_inst);

    /* 2. Signal the processing task that a frame has been received */
    /* Assuming 'rx_sem' is a semaphore initialized elsewhere */
    ca_sem_post(&rx_sem);

    /* 3. The task will later re-enable DMA using the appropriate driver
    function */
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_uart_hw_dma_rx_off in my caOS application?
A: You should call this function when transitioning from DMA-based reception to interrupt-based reception, typically in a DMA completion callback or upon a reception timeout. It is used to stop the DMA controller from requesting transfers and to enable the RX interrupt to handle individual bytes.

Code example conf:0.90 **Q:** How do I implement a transition from DMA to interrupt mode using caOS types?
A: You can use the following snippet: void handle_frame_end(USART_TypeDef *uart_inst) { ca_uart_hw_dma_rx_off(uart_inst); }

Parameters conf:1.00 **Q:** What are the requirements for the 'inst' parameter in ca_uart_hw_dma_rx_off?
A: The 'inst' parameter must be a pointer to a valid, initialized STM32 UART peripheral instance (e.g., USART1, USART2). It must be a valid peripheral base address.

HW differences conf:1.00 **Q:** Are there any differences in how ca_uart_hw_dma_rx_off is implemented across different STM32 families?
A: Yes, the implementation varies based on the register definitions for the RX interrupt enable bit. While F1xx, F4xx, and F7xx use the USART_CR1_RXNEIE bit, newer families like H5xx, H7xx, and U5xx use the USART_CR1_RXNEIE_RXFNEIE bit to enable the interrupt.

---

ca_uart_hw_dma_rx_on

Header: caos/drivers/inc/ca_glue_hw.h:312
GUARD: EN_CA_GLUE_HW

```
extern void ca_uart_hw_dma_rx_on(USART_TypeDef *inst); /* fase payload:
    RXNEIE off, CR3.DMAR on */
```

Enables UART DMA reception by disabling interrupt-based RX and activating the DMA request signal.

Parametri:

Nome	Tipo	Descrizione
inst	USART_TypeDef *	Pointer to the STM32 UART peripheral instance (e.g., USART1, USART2). Must be a valid, initialized hardware base address.

Ritorna:
void

Note:

- This function is non-blocking and executes immediately by modifying hardware registers. It is thread-safe only if the UART peripheral is not being accessed by other tasks or ISRs simultaneously. It is safe to call from an ISR, but it is typically used in the setup phase of a DMA transfer. The most common mistake is calling this function before the DMA channel has been properly configured and enabled, which can lead to immediate DMA errors or missed data. Ensure the UART peripheral clock is enabled and the GPIO pins are configured before calling this.

Uso:

- This function is used to transition the UART from a standard interrupt-driven mode to a high-performance DMA-driven mode. It is typically called immediately after configuring the DMA channel with ca_dma_copy_target to ensure the hardware is ready to stream incoming bytes directly into memory. It is part of the standard initialization sequence: 1) Configure DMA, 2) Call ca_uart_hw_dma_rx_on, 3) Wait for completion using ca_uart_dma_wait.

Esempio:

```
/* Example: Setting up a DMA buffer for UART reception */
#define RX_BUFFER_SIZE 64
u8 rx_buf[RX_BUFFER_SIZE];

void start_uart_dma_reception(USART_TypeDef *inst, u32 uart_num) {
    /* 1. Configure the DMA channel to move data from UART to memory */
    /* Note: ca_uart_hw_dma_rx_addr(inst) is a helper to get the data register
    address */
    if (ca_dma_copy_target(1, rx_buf, (void*)&inst->RDR, RX_BUFFER_SIZE, 0, 0))
    {
```

```
        /* 2. Switch UART to DMA mode: disable RX interrupts and enable DMA
    request */
        ca_uart_hw_dma_rx_on(inst);
    } else {
        /* Handle error: DMA channel busy or invalid */
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_uart_hw_dma_rx_on in my initialization sequence?
A: You should call it after configuring the DMA channel (e.g., using ca_dma_copy_target) but before waiting for completion with ca_uart_dma_wait. It is used to transition the UART from standard interrupt-driven mode to high-performance DMA-driven mode.

Code example conf:1.00 **Q:** Provide a minimal example of how to enable DMA reception for USART1.
A: void setup_uart_dma(void) { /* Assume DMA is already configured */ ca_uart_hw_dma_rx_on(U
}

Parameters conf:1.00 **Q:** What does the inst parameter represent and what are the requirements for it?
A: The inst parameter is a pointer to the STM32 UART peripheral instance (e.g., USART1, USART2). It must be a valid, initialized hardware base address. You must ensure the UART peripheral clock is enabled and the GPIO pins are configured before passing the pointer to this function.

HW differences conf:1.00 **Q:** Are there any differences in how ca_uart_hw_dma_rx_on handles register bits across different STM32 families?
A: Yes. For F1xx, F4xx, and F7xx families, the function clears the USART_CR1_RXNEIE bit. However, for H5xx, H7xx, and U5xx families, the function clears the USART_CR1_RXNEIE_RXFI bit instead, reflecting differences in the register definitions for those newer architectures.

`ca_uart_hw_dma_tx_addr`

Header: `caos/drivers/inc/ca_glue_hw.h:310`
GUARD: `EN_CA_GLUE_HW`

```
extern volatile void *ca_uart_hw_dma_tx_addr(USART_TypeDef *inst); /*
    indirizzo registro dati TX per il DMA (DR/TDR) */
```

Returns the memory address of the UART Transmit Data Register (TDR/DR) for DMA operations.

Parametri:

Nome	Tipo	Descrizione
`inst`	`USART_TypeDef *`	Pointer to the specific UART hardware instance (e.g., USART1, USART2). Must be a valid, initialized peripheral pointer.

Ritorna:
A volatile void pointer to the hardware register where data must be written for transmission. Returns NULL if the provided instance pointer is invalid.

Note:

- This function is a low-level hardware abstraction layer (HAL) helper. It is non-blocking, thread-safe, and can be called from an ISR because it performs a simple pointer arithmetic operation based on the architecture. It is strictly intended to provide the destination

address for DMA controllers. The most common mistake is passing a NULL or uninitialized peripheral pointer, which will cause a hard fault when the DMA controller attempts to access the address.

Uso:

- This function is used exclusively when configuring DMA transfers for UART transmission. It is typically paired with ca_dma_copy_target to link a memory buffer to the UART hardware peripheral. The sequence is: first, identify the UART instance; second, retrieve the TDR address using this function; third, pass that address to the DMA configuration function to initiate the hardware-managed data transfer.

Esempio:

```c
/* Example: Setting up a DMA transfer for UART1 */
#include "caos.h"

void send_data_via_dma(USART_TypeDef *uart_inst, ca_dma_ch_t tx_channel, uint8_t *data, uint16_t size) {
    /* Get the hardware register address for the UART TDR */
    volatile void *tx_reg_addr = ca_uart_hw_dma_tx_addr(uart_inst);

    if (tx_reg_addr != NULL) {
        /* Configure DMA to copy data from memory to the UART TDR register */
        if (ca_dma_copy_target(tx_channel, (void *)data, (void *)tx_reg_addr, size, CA_DMA_DIR_M2P, CA_DMA_WIDTH_8)) {
            /* Wait for the DMA transfer to complete before proceeding */
            ca_dma_wait(tx_channel);
        }
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use the ca_uart_hw_dma_tx_addr function in my caOS application?
A: You should use this function exclusively when configuring DMA transfers for UART transmission. It is intended to provide the destination address for the DMA controller, typically by being paired with ca_dma_copy_target to link a memory buffer to the UART peripheral.

Code example conf:1.00 **Q:** How do I retrieve the UART transmit register address for a DMA transfer?
A: You pass the UART instance pointer to the function as shown: volatile void *tx_addr = ca_uart_hw_dma_tx_addr(USART1);. Ensure the instance pointer is initialized and valid to avoid a hard fault.

Parameters conf:1.00 **Q:** What are the requirements for the 'inst' parameter in ca_uart_hw_dma_tx_addr?
A: The 'inst' parameter must be a pointer to a valid, initialized USART_TypeDef peripheral instance (e.g., USART1, USART2). Passing a NULL or uninitialized pointer is a common mistake that will cause a hard fault when the DMA controller attempts to access the returned address.

HW differences conf:1.00 **Q:** Are there differences in how this function handles register access across different STM32 families?
A: Yes, the function abstracts hardware-specific register naming. For F1xx and F4xx families, the function returns the address of the 'DR' register. For F7xx, H5xx, H7xx, and U5xx families, the function returns the address of the 'TDR' register.

ca_uart_hw_init

Header: caos/drivers/inc/ca_glue_hw.h:302
GUARD: EN_CA_GLUE_HW

```
extern bool ca_uart_hw_init(u32 uart_num, u32 baudrate, USART_TypeDef **
    _instance); /* inizializza il periferico UART al baudrate indicato */
```

Initializes a specific UART hardware peripheral, configures its baud rate, and enables its RX interrupt.

Parametri:

Nome	Tipo	Descrizione
uart_num	u32	The hardware index of the UART peripheral (e.g., 1 for USART1, 2 for USART2). Must match the hardware mapping of the specific STM32 series.
baudrate	u32	The desired communication speed in bits per second (e.g., 115200).
_instance	USART_TypeDef**	A pointer to a pointer that will be updated with the base address of the initialized hardware register block. Must not be NULL.

Ritorna:
Returns true if the peripheral was successfully identified, clocked, and configured. Returns false if the uart_num is invalid or the hardware instance cannot be resolved.

Note:

- This function is not thread-safe and should be called during system initialization before starting the OS scheduler. It is not intended to be called from an ISR. It performs low-level register manipulation, including enabling peripheral clocks in the RCC and configuring the NVIC for RX interrupts. A common mistake is passing an uninitialized pointer for _instance or attempting to re-initialize an already active UART without first ensuring no other tasks are using it. Note that this function does not configure GPIO pins; you must call ca_uart_configure_gpio separately to map the pins to the UART alternate function.

Uso:

- This function is the primary entry point for setting up serial communication. It is typically used in the board support package (BSP) initialization sequence. It is often paired with ca_uart_configure_gpio to set up the physical pins and ca_uart_retune if the system clock frequency changes dynamically. Once initialized, the returned instance pointer is used by other ca_uart_* functions to perform data transfers.

Esempio:

```
/* Example: Initializing USART2 for serial communication */
USART_TypeDef *my_uart = NULL;

// 1. Configure the physical pins for USART2 (e.g., PA2/PA3)
ca_uart_configure_gpio(2);

// 2. Initialize the hardware peripheral
if (ca_uart_hw_init(2, 115200, &my_uart)) {
    // Success: my_uart now points to the USART2 register base
    ca_printf("UART2 initialized successfully.\n");
} else {
    // Handle error: invalid UART number or hardware failure
    ca_printf("Failed to initialize UART2.\n");
}
```

Q&A — fine-tuning review *7/7 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_uart_hw_init() and why is it necessary?
A: You should call ca_uart_hw_init() during system initialization to configure a UART peripheral for communication. It's necessary because it sets up the hardware registers, enables the clock, configures the baud rate, and prepares the UART for data transmission and reception.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_uart_hw_init() with caOS types?
A:

```
USART_TypeDef* uart;
bool success = ca_uart_hw_init(1, 115200, &uart);
if (success) {
    // UART initialized successfully
    uart->TDR = 'A'; // Send a character
}
```

Parameters conf:0.85 **Q:** What does the 'uart_num' parameter represent and what are valid values?
A: The 'uart_num' parameter specifies which UART peripheral to initialize. Valid values are typically 1 through 8 depending on the MCU family. For example, on H7xx, valid values include 1, 2, 3, 4, 5, 6, 7, and 8, while on F7xx it may be limited to 1-6.

Return conf:0.90 **Q:** What does ca_uart_hw_init() return and what causes it to fail?
A: The function returns true on success and false on failure. Failures can occur if the uart_num is invalid, the hardware registers cannot be configured, or if the clock enabling fails.

Error/Edge case conf:0.80 **Q:** What are common mistakes or edge cases when using ca_uart_hw_init()?
A: Common mistakes include passing an invalid uart_num, not ensuring the system clock is properly configured before calling the function, or forgetting to enable the appropriate RCC clocks. Edge cases include attempting to initialize a UART that doesn't exist on the specific MCU or trying to initialize a UART that is already in use.

Behavior conf:0.85 **Q:** Is ca_uart_hw_init() blocking or non-blocking, and is it safe to call from an ISR?
A: The function is blocking as it performs hardware register writes and waits for configuration to complete. It is generally not ISR-safe because it modifies global hardware state and may involve system-level operations. It should be called from thread context during initialization.

HW differences conf:0.90 **Q:** How do the UART initialization functions differ between MCU families like F7xx, H7xx, and H7xx?
A: On F7xx, the function uses APB1ENR/APB2ENR for clock enabling and accesses standard USART registers. On H7xx, it uses APB1LENR/APB2ENR and includes a PRESC register for clock prescaling. Additionally, H7xx uses USART_CR1_RXNEIE_RXFNEIE for enabling RX interrupts, whereas F7xx uses USART_CR1_RXNEIE.

`ca_uart_hw_put`

Header: `caos/drivers/inc/ca_glue_hw.h:303`
GUARD: `EN_CA_GLUE_HW`

```
extern u16 ca_uart_hw_put(USART_TypeDef **_instance, p_str message); /*
    trasmette una stringa via UART in polling */
```

Transmits a string via UART using blocking polling mode.

Parametri:

Nome	Tipo	Descrizione
_instance	USART_TypeDef **	A pointer to the UART peripheral handle. Must not be NULL, and the dereferenced pointer must point to a valid initialized UART peripheral.
message	p_str	A pointer to a structure containing the data buffer and its size. Must not be NULL.

Ritorna:
Returns the number of bytes successfully sent (equal to message->size on success). Returns 0 if any input parameter is NULL or invalid.

Note:

- This function is strictly blocking; it waits in a 'while' loop for the hardware registers to be ready for each byte and for the final transmission to complete. Because it uses busy-waiting, it is NOT thread-safe if multiple tasks attempt to write to the same UART simultaneously, and it must NEVER be called from an ISR as it will cause a system hang. Ensure the UART peripheral has been initialized via ca_uart_init before calling this. A common mistake is passing a message structure with an uninitialized or zero-length buffer, which results in no data being sent.

Uso:

- This function is typically used for low-level debugging or simple serial communication where DMA is not required or available. It is often paired with ca_uart_configure_gpio to set up the pins before the first transmission. In the caOS architecture, it serves as the fallback transmission method when DMA resources are exhausted or when the message size is too small to justify the overhead of a DMA transfer.

Esempio:

```c
/* Assuming a message structure is already defined and populated */
extern USART_TypeDef *g_uart_instances[];

void send_debug_info(void) {
    p_str my_msg;
    /* Initialize message structure with data */
    my_msg.data = (u8 *)"System Ready\n";
    my_msg.size = 13;

    /* Ensure UART is configured before use */
    ca_uart_configure_gpio(1);

    /* Send the message via UART 1 in blocking mode */
    u16 sent = ca_uart_hw_put(&g_uart_instances[1], &my_msg);

    if (sent == 0) {
        /* Handle error: transmission failed or invalid parameters */
    }
}
```

Q&A — fine-tuning review *7/7 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_uart_hw_put for UART transmission?
A: Use ca_uart_hw_put when you need to send a string via UART in a polling mode, especially during debugging or system configuration where DMA or interrupt-based transmission is not feasible. It is suitable for non-critical timing scenarios where blocking behavior is acceptable.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_uart_hw_put?
A:

```
USART_TypeDef* uart_instance = USART1;
char msg[] = "Hello UART\n";
p_str message = { .data = (u8*)msg, .size = 12 };
ca_uart_hw_put(&uart_instance, &message);
```

Parameters conf:0.95 **Q:** What are the valid and invalid values for the parameters of ca_uart_hw_put?
A: The first parameter _instance must be a valid pointer to a USART_TypeDef pointer, and the USART instance must not be NULL. The second parameter message must be a valid p_str structure with a non-NULL data field and a positive size. Passing NULL for either parameter results in a return value of 0.

Return conf:0.95 **Q:** What does ca_uart_hw_put return in case of success and failure?
A: On success, ca_uart_hw_put returns the number of characters sent (message->size). On failure, it returns 0, which occurs when either _instance or message is NULL, or when the message structure is invalid.

Error/Edge case conf:0.90 **Q:** What are the common mistakes or edge cases when using ca_uart_hw_put?
A: Common errors include passing NULL pointers for _instance or message, not properly initializing the UART peripheral before calling the function, and attempting to call this function from an ISR, which is not allowed. Additionally, incorrect handling of buffer sizes or timeouts may lead to unexpected behavior.

Behavior conf:0.95 **Q:** Is ca_uart_hw_put blocking or non-blocking, and can it be called from an ISR?
A: ca_uart_hw_put is a blocking function that waits until all characters are transmitted. It is not safe to call from an ISR because it is blocking and could cause deadlocks or excessive delays in interrupt contexts.

HW differences conf:0.85 **Q:** How does ca_uart_hw_put differ between F7xx and H7xx microcontrollers?
A: On F7xx, the function uses ISR register bits like USART_ISR_TXE and USART_ISR_TC, and writes to TDR register. On H7xx, it also uses ISR register bits like USART_ISR_TXE_TXFNF and USART_ISR_TC, but with different naming conventions and writes to TDR register. The register access methods are consistent across families but differ in naming and bit positions.

`ca_uart_hw_recv_handler`

Header: `caos/drivers/inc/ca_glue_hw.h:304`
GUARD: `EN_CA_GLUE_HW`

```
extern u32 ca_uart_hw_recv_handler(USART_TypeDef **_instance, u32 *
    rx_data); /* gestore IRQ UART: legge il byte ricevuto dal registro DR
     */
```

Low-level hardware handler to read a single byte from the UART receive register.

Parametri:

Nome	Tipo	Descrizione
`_instance`	`USART_TypeDef **`	Pointer to the UART peripheral instance handle. Must not be NULL and must point to a valid initialized UART peripheral.
`rx_data`	`u32 *`	Pointer to a memory location where the received byte will be stored. Must not be NULL.

Ritorna:
Returns 0 if a byte was successfully read from the hardware register. Returns 1 if no data is available (RXNE flag not set) or if input pointers are invalid.

Note:

- This function is designed to be called directly from an Interrupt Service Routine (ISR) or a high-priority polling loop. It is non-blocking and performs a direct register read, making it extremely fast but also dangerous if called without checking the hardware status first. It is not thread-safe by itself; it assumes the caller has already verified that the UART peripheral is initialized and that an interrupt or status flag indicates data is ready. A common mistake is calling this function without checking the UART status flags, which may result in reading stale or invalid data if the hardware buffer is empty.

Uso:

- This function is the lowest level of the UART receive chain. It is typically invoked by the UART interrupt handler (the ISR) when the hardware signals that a byte has arrived. After reading the byte, the ISR usually passes the data to higher-level functions like ca_cli_rx_byte for command processing or a queue-based buffer system to store the data for later consumption by a task. It is never used in isolation; it is always part of a sequence: check status -> call ca_uart_hw_recv_handler -> process byte.

Esempio:

```c
void USART1_IRQHandler(void) {
    u32 rx_byte = 0;
    /* Check if the UART instance is valid and attempt to read the byte */
    if (ca_uart_hw_recv_handler(&g_uart_instances[0], &rx_byte) == 0) {
        /* Successfully read, pass the byte to the CLI system */
        ca_cli_rx_byte((u8)rx_byte);
    } else {
        /* Handle error or spurious interrupt if necessary */
    }
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_uart_hw_recv_handler in my UART interrupt service routine?

A: You should call ca_uart_hw_recv_handler from your UART ISR when you are certain that the RXNE (Receive Data Register Not Empty) flag is set. This function is designed to safely read a byte from the UART data register (DR/RDR) and is intended for use in interrupt contexts where hardware-driven UART reception occurs.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_uart_hw_recv_handler in a UART ISR?

A:

```c
u32 data;
USART_TypeDef* uart_instance = USART1;
if (ca_uart_hw_recv_handler(&uart_instance, &data) == 0) {
    // Process received byte in 'data'
}
```

Parameters conf:0.95 **Q:** What are the valid and invalid values for the _instance and rx_data parameters?

A: The _instance parameter must be a pointer to a valid USART_TypeDef*; passing NULL or a pointer to NULL will cause the function to return 1. The rx_data parameter must be a valid pointer to a u32 where the received byte will be stored; passing NULL will cause a crash.

Return conf:0.90 **Q:** What does it mean when ca_uart_hw_recv_handler returns 1?

A: A return value of 1 indicates either that no byte is available for reading (RXNE flag not set), or that one or more parameters passed to the function were invalid (e.g., _instance is NULL or points to NULL).

HW differences conf:0.85 **Q:** How does ca_uart_hw_recv_handler differ between F7xx and H7xx MCUs in terms of register usage?
A: On F7xx MCUs, the function checks the ISR register for the USART_ISR_RXNE flag and reads from the RDR register. On H7xx MCUs, it also checks the ISR register but uses the USART_ISR_RXNE_RXFNE flag and reads from the RDR register. The main difference is in the flag used to check for data availability.

`ca_uart_init`

Header: `caos/drivers/inc/uart.h:73`
Source: `caos/drivers/src/uart.c:108:190`
GUARD: `EN_UART`

```
bool ca_uart_init(u32 uart_num, u32 baudrate, ca_uart_rx_cb_t on_rx, u8
    alternate)
```

Initializes a hardware UART peripheral, configures its GPIO pins, and registers an optional RX callback.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The hardware index of the UART peripheral (e.g., 1 for USART1). Must be within the range [1, CA_UART_MAX).
`baudrate`	`u32`	The desired communication speed in bits per second (e.g., 115200).
`on_rx`	`ca_uart_rx_cb_t`	A function pointer to be called when data is received. Pass NULL if no callback is required.
`alternate`	`u8`	The alternate function mapping index for the GPIO pins. This determines which physical pins are assigned to the UART.

Ritorna:
Returns true if the UART and GPIO were successfully initialized, false otherwise (e.g., invalid uart_num or hardware configuration failure).

Note:

- This function is not thread-safe and should be called during system initialization before starting the OS scheduler. It performs hardware-level configuration, including GPIO setup, which is blocking and relies on underlying hardware registers. Do not call this function from an ISR, as it may perform operations that are not ISR-safe. A common mistake is passing an invalid uart_num or failing to ensure the peripheral clock is enabled, which will result in a false return value. Additionally, the 'alternate' parameter is critical; providing the wrong value can cause the UART to drive pins that are already in use by other board peripherals, potentially causing electrical conflicts.

Uso:

- Use this function during the early boot phase to prepare communication interfaces. It is typically paired with other initialization functions like ca_os_tick_init. Once initialized, the UART can be used for data transmission or command-line interfaces. It is common to call this once at startup to set the hardware state, after which the driver maintains the configuration for subsequent use with functions like ca_uart_put or ca_uart_dma_send.

Esempio:

```c
void system_init(void) {
    /* Define a callback for UART7 RX events */
    void on_rx_uart7(u8 data) {
        /* Handle incoming byte */
    }

    /* Initialize UART7 at 115200 baud with the RX callback and alternate pin map 1 */
    if (ca_uart_init(7, 115200, on_rx_uart7, 1)) {
        /* UART initialized successfully */
    } else {
        /* Handle initialization error */
    }
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_uart_init in a caOS project?
A: You should call ca_uart_init during system initialization, typically before starting any tasks that rely on UART communication. It is used to configure a specific UART peripheral with a given baudrate and an optional receive callback function.

Code example conf:0.95 **Q:** Can you show a minimal example of how to use ca_uart_init with caOS types?
A: u32 baudrate = 115200; bool success = ca_uart_init(1, baudrate, NULL); if (success) { // UART initialized successfully } else { // Handle initialization failure }

Parameters conf:0.90 **Q:** What are the valid values for uart_num in ca_uart_init?
A: The uart_num must be a value between 1 and CA_UART_MAX-1. Values 0 or greater than or equal to CA_UART_MAX will cause the function to fail. For example, if CA_UART_MAX is 4, valid values are 1, 2, and 3.

Return conf:0.95 **Q:** What does ca_uart_init return when it fails?
A: It returns false when initialization fails. This can happen if uart_num is invalid, or if there is a hardware initialization error.

Error/Edge case conf:0.90 **Q:** What are common mistakes when calling ca_uart_init?
A: Common mistakes include passing an invalid uart_num (0 or >= CA_UART_MAX), not configuring GPIOs with ca_uart_configure_gpio() before calling ca_uart_init, and using a baudrate that is not supported by the STM32 chip.

Behavior conf:0.90 **Q:** Is ca_uart_init thread-safe and can it be called from an ISR?
A: No, ca_uart_init is not thread-safe and must not be called from an ISR. It is a blocking function that should only be called from a task or main thread, and requires synchronization if called from multiple threads.

`ca_uart_init_dma`

Header: `caos/drivers/inc/uart.h:134`
Source: `caos/drivers/src/uart.c:295:335`
GUARD: `EN_UART`

```c
bool ca_uart_init_dma(u32 uart_num, u32 baudrate, ca_uart_rx_cb_t on_rx, u8 alternate)
```

Initializes a UART peripheral with DMA support for efficient, non-blocking data transmission and reception.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The hardware identifier for the UART peripheral (e.g., 1, 2, 3). Must not be 0.
`baudrate`	`u32`	The communication speed in bits per second (e.g., 115200).
`on_rx`	`ca_uart_rx_cb_t`	A pointer to the callback function executed when data is received via DMA.
`alternate`	`u8`	Selects the alternate GPIO pin mapping for the UART peripheral. Use 0 for default mapping.

Ritorna:
Returns true if the UART and DMA channels were successfully initialized and bound; returns false if the UART is already in use, no DMA channels are available, or hardware initialization fails.

Note:

- This function is not thread-safe and should be called during system initialization before starting the scheduler. It is not callable from an ISR because it performs resource allocation and hardware configuration. A common mistake is failing to ensure that the DMA controller has been initialized via ca_dma_init() before calling this function, which will cause the internal binding process to fail. The function handles the complex task of mapping UART hardware requests to available DMA channels, so you do not need to manually configure DMA registers.

Uso:

- Use this function when you need high-performance serial communication that does not block the CPU during data transfers. It is typically called once during the system startup phase, immediately after ca_dma_init(). It is often paired with other DMA-based UART functions for actual data movement, and the provided callback will be triggered by the DMA interrupt once a transfer completes. Ensure the UART peripheral is not already initialized or in use by another task before calling this function.

Esempio:

```
void system_init(void) {
    // Initialize DMA controller first
    ca_dma_init();

    // Define a callback for received data
    // void my_rx_callback(void *data, u32 len) { ... }

    // Initialize UART1 with DMA at 115200 baud using default pins
    if (!ca_uart_init_dma(1, 115200, my_rx_callback, 0U)) {
        // Handle initialization error
        ca_printf("UART DMA init failed!\n");
    }
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_uart_init_dma instead of standard UART functions?
A: You should use ca_uart_init_dma when you require high-performance serial communication that does not block the CPU during data transfers. It is designed for non-blocking operations and is typically called once during the system startup phase.

Code example conf:0.90 **Q:** How do I initialize UART1 with DMA in caOS?
A: void my_rx_callback(u8* data, u32 len) { /* Handle data */ } void init(void) { ca_dma_init(); ca_uart_init_dma(1, 115200, my_rx_callback); }

Parameters conf:1.00 **Q:** What are the constraints on the uart_num parameter?
A: The uart_num parameter represents the hardware identifier for the UART peripheral. It must be a value greater than 0 (e.g., 1, 2, or 3).

Return conf:1.00 **Q:** What does a return value of false indicate for ca_uart_init_dma?
A: A return value of false indicates that the initialization failed. This occurs if the UART is already in use, no DMA channels are available, or the hardware initialization fails.

Error/Edge case conf:1.00 **Q:** What is a common mistake that causes ca_uart_init_dma to fail?
A: A common mistake is failing to ensure that the DMA controller has been initialized via ca_dma_init() before calling ca_uart_init_dma(), which causes the internal binding process to fail.

Behavior conf:1.00 **Q:** Is ca_uart_init_dma safe to call from an interrupt service routine or multiple threads?
A: No, this function is not thread-safe and is not callable from an ISR because it performs resource allocation and hardware configuration. It must be called during system initialization before starting the scheduler.

`ca_uart_put`

Header: `caos/drivers/inc/uart.h:81`
Source: `caos/drivers/src/uart.c:189:204`
GUARD: `EN_UART`

```
u16 ca_uart_put(u32 uart_num, p_str message)
```

Transmits a message buffer over a specified UART peripheral.

Parametri:

Nome	Tipo	Descrizione
`uart_num`	`u32`	The index of the UART peripheral to use. Must be a valid index within the range [1, CA_UART_MAX - 1]. Passing 0 or an index out of bounds will result in an immediate return of 0.
`message`	`p_str`	A pointer to the message structure containing the data to send. Must not be NULL. The structure must have a valid size field.

Ritorna:
Returns a u16 value representing the status or number of bytes processed. Returns 0 if the UART index is invalid, the UART instance is not initialized, or the message pointer is NULL.

Note:

- This function acts as a high-level abstraction layer that automatically chooses between DMA-based transmission (if EN_UART_DMA is enabled and a DMA channel is found) or standard hardware-based transmission. It is not explicitly documented as thread-safe for concurrent access to the same UART instance, so ensure that multiple tasks do not attempt to write to the same UART simultaneously without external synchronization. It is generally not recommended to call this from an ISR unless the underlying driver implementation explicitly supports it, as it may involve blocking operations or resource contention. The most common beginner mistake is passing an uninitialized UART index or a NULL message pointer, which causes the function to fail silently by returning 0.

Uso:

- This function is typically used for sending formatted data, logs, or communication packets to external devices or debug consoles. In a standard workflow, you would first initialize the UART peripheral using ca_uart_init, then prepare your data in a buffer, and finally call ca_uart_put to transmit it. It is often paired with ca_uart_dbg_put when you want to send data specifically to the system's designated debug UART. It is frequently used in communication loops where a message is constructed, its size is set, and then it is passed to this function for transmission.

Esempio:

```c
/* Example: Sending a status message over UART */
#include "caos.h"

void send_status_update(void) {
    p_str msg;
    /* Allocate memory for the message structure */
    msg = ca_memory_allocate(sizeof(struct_p_str));
    if (msg == NULL) return;

    /* Prepare the message content */
    /* Assuming 'data_buffer' is a pre-filled array */
    msg->data = data_buffer;
    msg->size = 10;

    /* Send the message via UART 1 */
    u16 result = ca_uart_put(1, msg);

    if (result == 0) {
        /* Handle error: transmission failed or invalid UART */
    }

    /* Free the allocated message structure */
    ca_memory_free(msg);
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use the ca_uart_put function in a caOS application?
A: You should use ca_uart_put to send a string message via a specific UART interface in a caOS application. It is typically used for debugging, logging, or communication with external devices. The function is blocking, so it waits until the entire message is sent, making it suitable for scenarios where you need to ensure message delivery before proceeding.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_uart_put with caOS types?
A: u16 result = ca_uart_put(1, "Hello, caOS!\n"); if (result == 0) { /* Handle error */ } else { /* Success: sent result bytes */ }

Parameters conf:0.90 **Q:** What are the valid values for uart_num and what happens if I pass an invalid value?
A: The uart_num must be greater than 0 and less than CA_UART_MAX. If uart_num is invalid or if g_uart_instances[uart_num] is NULL, the function will return 0. The message parameter must not be NULL; otherwise, it also returns 0.

Return conf:0.95 **Q:** What does the return value of ca_uart_put indicate, and what causes it to return 0?
A: The function returns the number of bytes successfully sent if successful. It returns 0 in case of error, which occurs when uart_num is invalid, g_uart_instances[uart_num] is NULL, or when message is NULL.

ca_uart_recv_handler

Header: caos/drivers/inc/uart.h:94
Source: caos/drivers/src/uart.c:206:223
GUARD: EN_UART

```
void ca_uart_recv_handler(u32 uart_num)
```

Processes incoming UART data by routing it to the CLI or a registered callback function.

Parametri:

Nome	Tipo	Descrizione
uart_num	u32	The index of the UART peripheral. Must be a valid index within [1, CA_UART_MAX-1]. Values outside this range or 0 are ignored.

Ritorna:
void

Note:

- This function is designed to be called from within a UART hardware interrupt service routine (ISR). It is not thread-safe in the sense that it relies on the hardware state being consistent at the time of the interrupt. The function performs a non-blocking check on the hardware buffer; if data is available, it either passes it to the CLI (if the UART is configured for debugging) or triggers a user-defined callback hook. A common mistake is failing to initialize the UART instance or the callback hook before the interrupt fires, which results in the function silently returning without processing data.

Uso:

- This function is the core of the UART reception pipeline in caOS. It is typically invoked by the low-level hardware interrupt vector when a 'RXNE' (Receive Register Not Empty) event occurs. It pairs with ca_uart_init to set up the hardware and ca_cli_set_hook or a custom hook registration to define what happens to the received bytes. It acts as the bridge between raw hardware interrupts and the application-level logic.

Esempio:

```
/* Example of setting up a custom callback for UART 1 */

void my_rx_callback(u32 data) {
    /* Process the received byte */
    ca_printf("Received: %c\n", (char)data);
}

void setup_uart_processing(void) {
    /* Initialize UART hardware first */
    /* ca_uart_init(1, ...); */

    /* Register the callback to be triggered by ca_uart_recv_handler */
    /* hook_on_rx[1] = my_rx_callback; */
}

/* Inside the actual hardware interrupt handler for UART 1 */
void USART1_IRQHandler(void) {
    /* This function is called by the hardware when data arrives */
    ca_uart_recv_handler(1);
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_uart_recv_handler in my embedded application?
A: You should call ca_uart_recv_handler only from an interrupt service routine (ISR) when a byte is received on a UART. It is not meant to be called directly from a thread or main application code. The function is designed to inject received bytes into either a CLI or a custom user function, depending on how hook_on_rx is initialized.

Code example conf:0.90 **Q:** Can you provide a minimal example of how to use ca_uart_recv_handler with caOS types?
A:

```
u32 uart_num = 0;
ca_uart_recv_handler(uart_num);
```

Parameters conf:0.90 **Q:** What is the meaning of the uart_num parameter, and what are valid values?
A: The uart_num parameter specifies the UART number from which the byte was received. It must be a valid value between 0 and the maximum number of UARTs available. Using an invalid value may lead to undefined behavior such as memory access violations or incorrect handling of the received byte.

Error/Edge case conf:0.85 **Q:** What are common mistakes or edge cases when using ca_uart_recv_handler?
A: Common mistakes include calling this function directly from a thread instead of an ISR, which can cause undefined behavior. Additionally, if hook_on_rx is not properly initialized, the function may ignore the received byte. Using an invalid uart_num value can also lead to memory access violations or unpredictable behavior.

Behavior conf:0.90 **Q:** Is ca_uart_recv_handler blocking or non-blocking, and is it safe to use in a thread context?
A: ca_uart_recv_handler is non-blocking and is designed to be called from an ISR. It is not thread-safe because it modifies global variables and should not be invoked directly from a thread. It is intended to be fast and avoid any blocking operations.

`ca_uart_retune`

Header: `caos/drivers/inc/uart.h:73`
Source: `caos/drivers/src/uart.c:171:177`
GUARD: `EN_UART`

```
void ca_uart_retune(void)
```

Re-initializes all active UART peripherals to match the current system clock frequency.

Ritorna:
This function returns void and does not provide a status code.

Note:

- This function is intended to be called whenever the system clock configuration changes, such as during power-saving frequency scaling. It iterates through all registered UART instances and re-applies their baud rate settings using the current clock parameters. It is not thread-safe and should not be called from an ISR, as it performs hardware initialization which may involve blocking operations or shared resource access. A common mistake is calling this function before the UART hardware has been initialized at least once, which may lead to undefined behavior if the internal instance pointers are NULL.

Uso:

- This function is typically used within power management routines, specifically when the CPU frequency is scaled up or down to save energy. It is usually paired with ca_os_clock_reduce_freq

or ca_os_clock_restore_freq to ensure that serial communication remains stable after the peripheral clock source changes. In a typical sequence, you would call ca_os_clock_reduce_freq to change the system speed, followed by ca_uart_retune to update the UART baud rate generators, and finally ca_os_tick_retune to adjust the OS heartbeat.

Esempio:

```
void adjust_system_performance(u16 scale_factor) {
    /* Reduce system clock frequency to save power */
    ca_os_clock_reduce_freq(scale_factor);

    /* Update OS tick timing to match new clock */
    ca_os_tick_retune();

    /* Re-calculate and apply baud rates for all active UARTs */
    ca_uart_retune();

    /* If CAN bus is used, update its timing as well */
    ca_can_retune();
}
```

Q&A — fine-tuning review *2/2 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_uart_retune in my application?
A: You should call ca_uart_retune whenever the system clock configuration changes, such as during power-saving frequency scaling. It is typically used in power management routines after calling ca_os_clock_reduce_freq or ca_os_clock_restore_freq to ensure serial communication remains stable after the peripheral clock source changes.

Code example conf:0.95 **Q:** How do I implement a frequency scaling routine using ca_uart_retune?
A: To scale the system frequency, you must update the clock and then re-tune the peripherals. Example: { ca_os_clock_reduce_freq(); ca_uart_retune(); ca_os_tick_retune(); } Note that this function is not thread-safe and must not be called from an ISR.

`ca_udp_client_connect`

Header: `caos/net/inc/udp_client.h:80`
Source: `caos/net/src/udp_client.c:183:229`
GUARD: `EN_UDP_CLIENT`

```
u8 ca_udp_client_connect(const ca_udp_client_cfg_t *cfg)
```

Initializes and registers a new UDP client instance to enable network communication.

Parametri:

Nome	Tipo	Descrizione
`cfg`	`const ca_udp_client_cfg_t *`	Pointer to a configuration structure containing server IP, ports, and callback functions. Must not be NULL.

Ritorna:
Returns a 1-based handle (1 to UDPCLI_MAX_HANDLES) on success, or 0 if the connection fails or no slots are available.

Note:

- This function is thread-safe as it uses an internal mutex to manage slot allocation. It is NOT callable from an ISR because it performs blocking operations like mutex locking and potential network resolution. You must ensure the network stack is initialized before

calling this. A common mistake is failing to check the return value; if it returns 0, the client was not created, and subsequent calls to send or receive using that handle will fail.

Uso:

- This function is the entry point for UDP communication. It is typically called during system initialization or when a task needs to establish a connection to a remote server. It is used in a sequence: first, populate the configuration struct, then call this function to get a handle, use the handle for ca_udp_client_send and ca_udp_client_recv, and finally call ca_udp_client_disconnect to release the slot when finished.

Esempio:

```
ca_udp_client_cfg_t cfg;
ca_udp_client_cfg_t *my_client;

/* Initialize configuration struct */
ca_memzero(&cfg, sizeof(cfg));
cfg.server_ip = 0x0A000001; // Example IP: 10.0.0.1
cfg.server_port = 8080;
cfg.local_port = 0; // Let system assign ephemeral port

/* Attempt to connect */
u8 handle = ca_udp_client_connect(&cfg);

if (handle > 0) {
    // Connection successful, use 'handle' for communication
    // ca_udp_client_send(handle, data, len);
} else {
    // Handle error: log failure or retry
    ca_printf("Failed to connect UDP client\n");
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_client_connect and what is its purpose in a caOS application?
A: You should call ca_udp_client_connect after initializing the network stack with cli_init_once to create a UDP client that connects to a remote server. It is used to establish a UDP communication channel with a server by providing configuration details such as server IP, port, and local network settings. The function returns an handle that can be used to manage the client.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_udp_client_connect with caOS types?
A: ca_udp_client_cfg_t cfg; cfg.server_ip = 0xC0A80101U; // 192.168.1.1 cfg.server_port = 12345U; cfg.local_ip = 0xC0A80102U; // 192.168.1.2 cfg.local_mac = 0x123456789ABCULL; cfg.arp_timeout_ms = 1000U; cfg.rx_callback = NULL; u8 handle = ca_udp_client_connect(&cfg); if (handle > 0U) { // Client created successfully with handle = handle } else { // Failed to create client }

Parameters conf:0.90 **Q:** What does the cfg parameter in ca_udp_client_connect represent and what are valid values?
A: The cfg parameter is a pointer to a ca_udp_client_cfg_t structure that holds configuration details for the UDP client. It must not be NULL. Valid values include a valid server IP address, a valid server port, correct local IP and MAC addresses, and a valid ARP timeout value. The structure must be initialized before calling the function.

Return conf:0.95 **Q:** What do the return values of ca_udp_client_connect mean and what causes a failure?
A: A return value of 0U indicates failure due to NULL config pointer, no free slots, bind failure, or ARP resolution failure. Return values from 1U to UDPCLI_MAX_HANDLES

indicate success, with the value being the handle of the created UDP client. The handle is 1-based, so the first client has handle = 1.

Error/Edge case conf:0.90 **Q:** What are common error conditions or mistakes when using ca_udp_client_connect?

A: Common errors include passing a NULL pointer to cfg, not having available slots for a new client, ARP resolution timeout, bind failure, or incorrect IP/mac address configuration. These can lead to a return value of 0U, indicating failure to create the UDP client.

Behavior conf:0.95 **Q:** Is ca_udp_client_connect blocking or non-blocking, and is it safe to call from an ISR?

A: ca_udp_client_connect is a blocking function because it waits for mutex acquisition and ARP resolution (if enabled). It is not safe to call from an ISR because it is not ISR-safe and uses mutexes, which are not suitable for interrupt context.

`ca_udp_client_disconnect`

Header: `caos/net/inc/udp_client.h:100`
Source: `caos/net/src/udp_client.c:275:290`
GUARD: `EN_UDP_CLIENT`

```
1 void ca_udp_client_disconnect(u8 handle)
```

Terminates an active UDP client session, releases associated network buffers, and unbinds the local port.

Parametri:

Nome	Tipo	Descrizione
`handle`	`u8`	The unique identifier returned by ca_udp_client_connect. Valid range is 1 to UDPCLI_MAX_HANDLES. Passing 0 or an out-of-bounds value will result in a silent failure.

Ritorna:
void

Note:

- This function is thread-safe as it uses an internal mutex to protect the client slot state. It is a blocking operation because it must acquire the mutex and potentially iterate through pending network buffers to free them. It must NOT be called from an ISR (Interrupt Service Routine) because blocking calls are forbidden in interrupt context. A common mistake is to call this function without having previously initialized the UDP client system or using an invalid handle, which leads to memory leaks if buffers are not properly cleaned up or undefined behavior if the handle points to an uninitialized slot.

Uso:

- This function is used to gracefully shut down a UDP client when communication is no longer needed or when a connection error occurs. It is typically the final step in the lifecycle of a UDP client: ca_udp_client_connect -> ca_udp_client_recv/send -> ca_udp_client_disconnect. It ensures that the local port is released back to the system and that any memory allocated for queued packets is returned to the heap, preventing memory exhaustion.

Esempio:

```c
u8 my_udp_handle = 0;

// Initialize connection
my_udp_handle = ca_udp_client_connect(12345, 0x0A000001, 8080);

if (my_udp_handle != 0) {
    // ... perform network operations ...

    // Disconnect and clean up resources
    ca_udp_client_disconnect(my_udp_handle);
    my_udp_handle = 0;
} else {
    // Handle connection failure
    ca_printf("Failed to connect UDP client\n");
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_client_disconnect() in my UDP client application?
A: You should call ca_udp_client_disconnect() when you want to close a UDP client connection and free up the associated local port. This is typically done when the client is no longer needed, such as after completing a communication session or when shutting down the application.

Code example conf:0.90 **Q:** Can you show a minimal C code example using ca_udp_client_disconnect() with caOS types?
A: u8 handle = 1; ca_udp_client_disconnect(handle);

Parameters conf:0.90 **Q:** What is the valid range for the handle parameter in ca_udp_client_disconnect()?
A: The handle parameter must be an unsigned 8-bit integer (u8) in the range [1, UDPCLI_MAX_HANDLES], inclusive. If handle is 0 or greater than UDPCLI_MAX_HANDLES, the function does nothing.

Error/Edge case conf:0.95 **Q:** What happens if I call ca_udp_client_disconnect() with an invalid handle value?
A: If the handle is 0 or greater than UDPCLI_MAX_HANDLES, the function will ignore the input and perform no operation. It does not return an error code or throw an exception.

Behavior conf:0.85 **Q:** Is ca_udp_client_disconnect() thread-safe and ISR-safe?
A: The function is not thread-safe if called from an ISR. It is also blocking, as it may wait to acquire a mutex. It is not safe to call this function from an ISR, and it should only be used when the handle has been correctly allocated.

`ca_udp_client_recv`

Header: `caos/net/inc/udp_client.h:93`
Source: `caos/net/src/udp_client.c:244:273`
GUARD: `EN_UDP_CLIENT`

```c
bool ca_udp_client_recv(u8 handle, u8 *buf, u16 buf_len, u16 *out_len,
    u32 timeout_ms)
```

Blocks the calling task until a UDP packet is received on the specified client handle or the timeout expires.

Parametri:

Nome	Tipo	Descrizione
handle	u8	The unique ID of the UDP client session. Must be between 1 and UDPCLI_MAX_HANDLES.
buf	u8 *	Pointer to the destination buffer where the received payload will be copied.
buf_len	u16	Size of the destination buffer in bytes.
out_len	u16 *	Pointer to store the actual number of bytes copied. Can be NULL if not needed.
timeout_ms	u32	Maximum time to wait in milliseconds. Use 0 for no wait or a large value for indefinite blocking.

Ritorna:
Returns true if a packet was successfully received and copied to the buffer. Returns false if the handle is invalid, the client is inactive, the operation timed out, or the internal buffer is invalid.

Note:

- This function is blocking; it puts the calling task into a waiting state until data arrives or the timeout occurs. It is NOT safe to call from an ISR because it performs blocking operations (semaphores and mutexes). Ensure the UDP client has been initialized and connected via ca_udp_client_connect before calling this. A common mistake is passing a buffer that is too small, which will result in truncated data without an error flag, or failing to check the return value, leading to processing uninitialized data.

Uso:

- This function is typically used in a dedicated network task loop to continuously poll for incoming UDP data. It is usually paired with ca_udp_client_connect to establish the session and ca_udp_client_send to transmit data. After receiving, the application processes the buffer and then waits for the next packet. It is the standard way to implement a request-response pattern where the client waits for a server reply.

Esempio:

```
u8 my_handle = 1; // Assume handle 1 is already connected
u8 rx_buffer[128];
u16 received_bytes = 0;

// Wait up to 500ms for a response
if (ca_udp_client_recv(my_handle, rx_buffer, sizeof(rx_buffer), &received_bytes,
    500)) {
    // Successfully received data
    ca_printf("Received %d bytes\n", received_bytes);
} else {
    // Handle timeout or error
    ca_printf("No data received or error occurred\n");
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_udp_client_recv in a caOS application?
A: You should use ca_udp_client_recv when you need to receive data from a UDP client in a caOS application. It is designed for blocking reception of UDP data with configurable timeout, making it suitable for applications where you want to wait for incoming packets without busy-waiting.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_udp_client_recv?
A: u8 handle = 1; u8 buffer[1024]; u16 received_len; bool result = ca_udp_client_recv(handle, buffer, sizeof(buffer), &received_len, 1000); if (result) { /* Process received data */ }

Parameters conf:0.95 **Q:** What are the valid ranges for the handle parameter in ca_udp_client_recv?

A: The handle must be between 1 and UDPCLI_MAX_HANDLES inclusive. If handle is 0 or greater than UDPCLI_MAX_HANDLES, the function returns false.

Return conf:0.90 **Q:** What does it mean when ca_udp_client_recv returns false?
A: ca_udp_client_recv returns false if there's an error such as an invalid handle, a NULL buffer, a timeout occurred, or if the client is not active. It also returns false if the client is in 'on_rx' mode or if the function is called from an ISR.

Error/Edge case conf:0.85 **Q:** What are common mistakes when using ca_udp_client_recv?
A: Common mistakes include passing a handle of 0 or greater than UDPCLI_MAX_HANDLES, passing a NULL buffer, not checking the return value when timeout_ms is 0, and calling the function from an ISR. Also, not handling the case where out_len is NULL can lead to errors.

Behavior conf:0.90 **Q:** Is ca_udp_client_recv thread-safe and can it be called from an ISR?
A: Yes, ca_udp_client_recv is thread-safe because it uses mutexes to protect shared data structures. However, it is NOT safe to call from an ISR because it uses semaphores and mutexes that may cause issues in interrupt contexts.

`ca_udp_client_refresh_mac`

Header: `caos/net/inc/udp_client.h:106`
Source: `caos/net/src/udp_client.c:292:315`
GUARD: `EN_UDP_CLIENT`

```
bool ca_udp_client_refresh_mac(u8 handle, u32 arp_timeout_ms)
```

Forces an update of the cached MAC address for a specific UDP client handle by performing an ARP resolution.

Parametri:

Nome	Tipo	Descrizione
`handle`	`u8`	The identifier of the UDP client slot. Must be between 1 and UDPCLI_MAX_HANDLES. Values outside this range will cause the function to return false.
`arp_timeout_ms`	`u32`	Maximum time in milliseconds to wait for the ARP resolution to complete. If the network is slow or the target is unreachable, the function will block for up to this duration.

Ritorna:
Returns true if the MAC address was successfully resolved and updated in the client slot. Returns false if the handle is invalid, the client is not active, or the ARP resolution failed (e.g., timeout reached).

Note:

- This function is blocking because it waits for the network stack to resolve the IP address via ARP. It is thread-safe as it uses internal mutexes to protect the client slot data, but it must NOT be called from an ISR (Interrupt Service Routine) because blocking operations are forbidden in ISR context. A common mistake is to call this function with an extremely short timeout, which will cause it to fail frequently on busy networks. Ensure the UDP client has been initialized and is in an active state before calling this.

Uso:

- This function is typically used when a UDP client detects that communication with the server has failed or when the network topology has changed, requiring a fresh ARP lookup.

It is usually called after a failed 'ca_udp_client_send' attempt. The typical sequence is: 1) Check if the client is active, 2) Call 'ca_udp_client_refresh_mac' to update the ARP cache, 3) Retry the network operation if the refresh succeeds.

Esempio:

```
u8 my_handle = 1; // Assume handle 1 is already initialized
u32 timeout = 500; // 500ms timeout

// Attempt to refresh the MAC address before sending data
if (ca_udp_client_refresh_mac(my_handle, timeout)) {
    // MAC updated successfully, safe to proceed with communication
    // ca_udp_client_send(my_handle, data, len);
} else {
    // Handle error: log failure or notify system
    ca_printf("Failed to refresh MAC for client %d\n", my_handle);
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_client_refresh_mac() in my UDP client application?
A: You should call ca_udp_client_refresh_mac() when you need to update the MAC address of a UDP server, especially after a network reconnection or when verifying the server's presence on the network. It is useful in scenarios where the server's MAC address might have changed or become stale.

Code example conf:0.90 **Q:** Can you show a minimal C code example using ca_udp_client_refresh_mac()?
A: u8 handle = 1; bool success = ca_udp_client_refresh_mac(handle, 1000); if (success) { // MAC address updated successfully } else { // Handle failure }

Parameters conf:0.90 **Q:** What does the arp_timeout_ms parameter control in ca_udp_client_refresh_mac()?
A: The arp_timeout_ms parameter sets the timeout in milliseconds for the ARP request. If set to 0, the function uses a default timeout value. Valid values are any positive integer, including 0, but the function will fail if the handle is invalid or the client is inactive.

Return conf:0.95 **Q:** What does it mean when ca_udp_client_refresh_mac() returns false?
A: A return value of false indicates that the MAC address update failed. This can happen due to an invalid handle, an inactive client, or a failed ARP request. If EN_ARP_SERVICE is disabled, the function will also return false if ARP fails.

Error/Edge case conf:0.85 **Q:** What are common mistakes when using ca_udp_client_refresh_mac()?
A: Common mistakes include passing an invalid handle (less than 1 or greater than UDPCLI_MAX_HANDLES), calling the function on an uninitialized or inactive client, or calling it from an ISR. Additionally, not ensuring that EN_ARP_SERVICE is enabled if ARP is required will cause the function to return false.

Behavior conf:0.90 **Q:** Is ca_udp_client_refresh_mac() thread-safe and ISR-safe?
A: Yes, the function is thread-safe as it uses a mutex to protect shared data structures. However, it is not ISR-safe and must not be called from an ISR because it uses mutexes and network functions that could cause deadlocks or undefined behavior.

`ca_udp_client_send`

Header: `caos/net/inc/udp_client.h:86`
Source: `caos/net/src/udp_client.c:231:242`
GUARD: `EN_UDP_CLIENT`

```
bool ca_udp_client_send(u8 handle, const u8 *payload, u16 len)
```

Sends a UDP payload using a previously initialized and connected client handle.

Parametri:

Nome	Tipo	Descrizione
`handle`	`u8`	The 1-based identifier returned by a successful connection function. Must be within the range [1, UDPCLI_MAX_HANDLES].
`payload`	`const u8 *`	Pointer to the buffer containing the data to be transmitted.
`len`	`u16`	The number of bytes to send from the payload buffer.

Ritorna:
Returns true if the packet was successfully queued for transmission, false if the handle is invalid, the client is not active, or the transmission failed.

Note:

- This function is thread-safe as it uses a mutex to check the client's active status. It is NOT callable from an ISR because it performs a mutex lock operation, which can cause the calling task to block. The function assumes the client has been properly initialized and connected; calling this with an uninitialized handle will result in a false return. A common mistake is passing a null pointer or an incorrect length, which may lead to memory access violations or truncated packets.

Uso:

- This function is used in the data transmission phase of a network application. It is typically paired with ca_udp_client_connect to establish the session and ca_udp_client_disconnect to clean up resources. In a typical workflow, the application initializes the client, connects to a remote endpoint, enters a loop to send data using this function, and finally disconnects when the communication is complete.

Esempio:

```
/* Assuming handle was obtained via a connection function */
u8 my_handle = 1;
const u8 data[] = "Hello, caOS!";

/* Check if the client is ready and send data */
if (ca_udp_client_send(my_handle, data, sizeof(data))) {
    /* Transmission successful */
} else {
    /* Handle error: log or retry */
    ca_printf("Failed to send UDP packet\n");
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_udp_client_send in a caOS-based embedded application?
A: You should call ca_udp_client_send when you need to transmit UDP packets from a pre-configured UDP client in your caOS application. It is typically used after initializing and activating a UDP client with ca_udp_client_init and ca_udp_client_activate, and is suitable for sending data over a network connection in a non-blocking manner.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_udp_client_send with caOS types?
A: u8 handle = 1; const u8 payload[] = {0x01, 0x02, 0x03}; u16 len = 3; bool success = ca_udp_client_send(handle, payload, len); if (success) { // Packet sent successfully } else { // Failed to send packet }

Parameters conf:0.95 **Q:** What are the valid ranges for the handle parameter in ca_udp_client_send?
A: The handle parameter must be a value between 1 and UDPCLI_MAX_HANDLES (inclusive). Using a value of 0 or any number greater than UDPCLI_MAX_HANDLES will cause the function to return false. The handle identifies a specific UDP client instance that must have been initialized and activated before calling this function.

Return conf:0.90 **Q:** What does it mean when ca_udp_client_send returns false?
A: A return value of false indicates that the packet transmission failed. This can happen due to invalid handle, a client that is not active, a NULL payload pointer, or a zero length. It does not necessarily mean the network is down, but rather that the function could not proceed with sending the data based on the provided parameters.

Error/Edge case conf:0.85 **Q:** What are the most common mistakes developers make when calling ca_udp_client_send?
A: Common mistakes include passing an invalid handle (0 or greater than UDPCLI_MAX_HANDLES), using a NULL payload pointer, calling the function on a UDP client that has not been activated, or attempting to call this function from an ISR. These errors will result in the function returning false and failing to send the packet.

`ca_udp_server_bind`

Header: `caos/net/inc/udp_server.h:95`
Source: `caos/net/src/udp_server.c:331:335`
GUARD: `EN_UDP_SERVER`

```
bool ca_udp_server_bind(void)
```

Registers the UDP server port and assigns a callback function to handle incoming network packets.

Ritorna:
Returns true if the port was successfully bound to the UDP handler, or false if the port configuration is invalid (e.g., port 0) or the binding process failed.

Note:

- This function is not thread-safe and must be called during the system initialization phase before the network stack starts processing traffic. It is not intended to be called from an Interrupt Service Routine (ISR). The function relies on a pre-configured static structure (s_srv_cfg) which must be initialized before calling this; failing to do so will result in a return value of false. A common beginner mistake is attempting to call this function before the network stack has been initialized via ca_net_proto_init, which will cause the binding to fail silently or return an error.

Uso:

- This function is typically used in the main initialization sequence of a network-enabled task. It is usually paired with ca_net_proto_init to prepare the stack, followed by ca_udp_server_bind to open the listening port. After binding, developers often call ca_eth_link_poll to ensure the physical link is active and ca_arp_send_garp to announce the device's presence on the network. It is essential to ensure the port is defined in the configuration before invocation.

Esempio:

```
/* Initialize the network stack first */
ca_net_proto_init(&net_cfg);

```

```
/* Attempt to bind the UDP server to the configured port */
if (ca_udp_server_bind()) {
    ca_stdout_printf_n("UDP server successfully bound");
} else {
    ca_stdout_printf_n("Failed to bind UDP server");
}

/* Ensure the link is polled to process incoming packets */
ca_eth_link_poll();
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_server_bind() in my UDP server implementation?
A: You should call ca_udp_server_bind() after you have configured the UDP server port, typically after setting up the server's IP address and port number. This function binds the specified port for receiving UDP packets and is essential for the server to start listening for incoming data.

Code example conf:0.90 **Q:** Can you provide a minimal C example using ca_udp_server_bind() with caOS types?
A: u16 port = 12345; // Assume UDP server is already configured with IP and port bool result = ca_udp_server_bind(); if (result) { // Binding successful } else { // Binding failed }

Return conf:0.90 **Q:** What does it mean when ca_udp_server_bind() returns false?
A: The function returns false if the port is 0 or if the binding operation fails. A return value of false indicates that the UDP server was not able to bind to the specified port, which could be due to incorrect configuration or a system-level failure during the binding process.

`ca_udp_server_client_count`

Header: `caos/net/inc/udp_server.h:120`
Source: `caos/net/src/udp_server.c:369:378`
GUARD: `EN_UDP_SERVER`

```
u8 ca_udp_server_client_count(void)
```

Returns the current number of active UDP server clients.

Ritorna:
Returns an unsigned 8-bit integer (u8) representing the count of currently assigned UDP clients. The value will always be between 0 and UDPSRV_MAX_CLIENTS.

Note:

- This function is thread-safe because it uses a mutex to protect the internal client list while iterating. It is a blocking call because it must wait for the mutex to be available; therefore, it must NEVER be called from an ISR (Interrupt Service Routine) or a critical section, as this would cause a system deadlock or crash. The UDP server must be initialized before calling this function. A common mistake is assuming the count remains constant after the function returns; in a multi-threaded environment, a client could disconnect or connect immediately after the function returns, so treat the result as a snapshot in time.

Uso:

- This function is typically used for system monitoring, diagnostics, or telemetry reporting. It is often paired with CLI commands to display server status or included in periodic system

health logs to track network load. Developers use it to verify if the server is reaching its maximum capacity or to detect if clients are failing to disconnect properly, which might indicate a memory or resource leak.

Esempio:

```c
/* Example: Periodic diagnostic task to monitor UDP server load */
void monitor_task(void *pvParameters) {
    while (1) {
        u8 active_clients = ca_udp_server_client_count();

        /* Log the current number of clients to the system console */
        ca_stdout_printf_n("System Status: Active UDP clients = %u", (u32)
    active_clients);

        /* Check if we are nearing capacity */
        if (active_clients > 10) {
            ca_stdout_printf_n("Warning: High UDP client load detected!");
        }

        /* Wait for 5 seconds before the next check */
        ca_os_delay_ms(5000);
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_server_client_count() and why is it important for managing UDP connections?
A: You should call ca_udp_server_client_count() when you need to monitor or control the number of active UDP clients connected to your server. This function is important because it provides a thread-safe way to retrieve the current client count, protecting access to internal data structures using a mutex. It helps in managing resources and understanding connection load, especially in applications where connection limits or dynamic behavior based on client count is required.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_udp_server_client_count() with caOS types?
A: u8 client_count; client_count = ca_udp_server_client_count(); if (client_count == 0) { // No clients connected } else { // Process client count }

Return conf:0.90 **Q:** What does the return value of ca_udp_server_client_count() indicate, and what can cause the function to return 0?
A: The return value of ca_udp_server_client_count() indicates the number of currently connected UDP clients, represented as a u8 value from 0 to 255. A return value of 0 can occur if the mutex protecting the internal data structure cannot be acquired, which may lead to a blocking condition or an error if the mutex is already locked by another thread. The function does not return explicit error codes, so improper use or mutex contention can result in a return value of 0 without indicating a specific failure reason.

`ca_udp_server_disconnect`

Header: `caos/net/inc/udp_server.h:115`
Source: `caos/net/src/udp_server.c:354:367`
GUARD: `EN_UDP_SERVER`

```c
void ca_udp_server_disconnect(u8 client_id)
```

Forcefully disconnects a specific UDP client and clears its associated network buffers.

Parametri:

Nome	Tipo	Descrizione
`client_id`	`u8`	The index of the client to disconnect. Must be less than UDPSRV_MAX_CLIENTS.

Ritorna:
void

Note:

- This function is thread-safe as it uses a mutex to protect the client state during modification. It is a blocking operation because it must acquire the server mutex and iterate through the client's ring buffer to free pending packets. It must NOT be called from an ISR (Interrupt Service Routine) because mutex locking is prohibited in interrupt context. A common mistake is passing an invalid client_id, which the function handles by returning early, but developers should always validate the ID before calling to ensure the intended client is actually the one being disconnected.

Uso:

- This function is typically used in network management tasks, such as a CLI command to 'kick' a misbehaving client or during a system shutdown sequence to clean up resources. It is often paired with ca_udp_server_get_client to verify the client exists before attempting to disconnect it. By clearing the ring buffer, it ensures that no stale data remains in memory, preventing potential memory leaks or processing of old packets if the same client slot is reused later.

Esempio:

```c
/* Example: Kicking a client via CLI command */
u8 id = 2; // Assume we want to disconnect client index 2
ca_udp_srv_client_info_t info;

// First, check if the client is actually connected
if (ca_udp_server_get_client(id, &info)) {
    // Disconnect the client and free its buffers
    ca_udp_server_disconnect(id);
    ca_printf_n("Client %u disconnected successfully.", (u32)id);
} else {
    ca_printf_n("Client %u is not active.", (u32)id);
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_server_disconnect() and what is its purpose in a UDP server implementation?
A: You should call ca_udp_server_disconnect() when you want to explicitly disconnect a specific UDP client from the server. Its purpose is to free up resources associated with that client, such as buffers and connection state. This function is typically used when a client session ends or needs to be terminated for any reason, ensuring proper cleanup of allocated memory and preventing resource leaks.

Code example conf:0.90 **Q:** Can you provide a minimal C code example showing how to use ca_udp_server_disconnect() with caOS types?
A: u8 client_id = 0; ca_udp_server_disconnect(client_id);

Parameters conf:0.95 **Q:** What is the significance of the client_id parameter in ca_udp_server_disconnect(), and what are the valid ranges for this value?
A: The client_id parameter identifies which specific UDP client to disconnect. It must be a value between 0 and UDPSRV_MAX_CLIENTS-1. If client_id is greater than or equal to UDPSRV_MAX_CLIENTS, the function will simply return without taking

any action. This ensures that only valid client indices are processed, preventing access to invalid memory locations.

Error/Edge case conf:0.90 **Q:** What are the potential issues or mistakes when using ca_udp_server_disconnect and what edge cases should be considered?
A: A common mistake is calling ca_udp_server_disconnect() with an invalid client_id (i.e., greater than or equal to UDPSRV_MAX_CLIENTS), which will cause the function to silently return without performing any action. Additionally, calling this function from an ISR is not allowed since it's blocking due to mutex usage. It's also important to ensure that the client was previously allocated and registered; otherwise, calling this function may lead to undefined behavior due to accessing uninitialized memory.

`ca_udp_server_get_client`

Header: `caos/net/inc/udp_server.h:133`
Source: `caos/net/src/udp_server.c:380:391`
GUARD: `EN_UDP_SERVER`

```
bool ca_udp_server_get_client(u8 client_id, ca_udp_srv_client_info_t *
    info)
```

Retrieves connection details for a specific UDP server client slot.

Parametri:

Nome	Tipo	Descrizione
`client_id`	`u8`	The index of the client slot to query. Must be less than UDPSRV_MAX_CLIENTS.
`info`	`ca_udp_srv_client_info_t *`	Pointer to a structure where the client data will be copied. Must not be NULL.

Ritorna:
Returns true if the client slot is currently assigned (connected), false otherwise. Also returns false if the provided pointer is NULL or the client_id is out of range.

Note:

- This function is thread-safe as it uses an internal mutex to protect the client table during the copy operation. It is a blocking function because it waits for the mutex; therefore, it must NEVER be called from an ISR (Interrupt Service Routine). A common mistake is to assume the client remains connected after the function returns; since the network state can change asynchronously, always check the 'connected' field in the returned structure before using the IP or port data.

Uso:

- This function is typically used in diagnostic tasks or CLI commands to iterate through all available client slots to display network status. It is usually paired with a loop that checks every index from 0 to UDPSRV_MAX_CLIENTS. It is the standard way to safely extract connection metadata (IP, port, and buffer usage) from the UDP server's internal state without causing race conditions.

Esempio:

```
void print_active_udp_clients(void) {
    ca_udp_srv_client_info_t info;
    for (u8 i = 0; i < 8; i++) {
        /* Attempt to retrieve client info for slot i */
        if (ca_udp_server_get_client(i, &info)) {
            /* Use ca_printf to display the client's IP address */
```

```
            ca_printf("Client %u connected: %u.%u.%u.%u\n",
                      (u32)i,
                      info.src_ip.v[0], info.src_ip.v[1],
                      info.src_ip.v[2], info.src_ip.v[3]);
        } else {
            /* Slot is empty or invalid */
            ca_printf("Client %u is inactive.\n", (u32)i);
        }
    }
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_udp_server_get_client in a caOS-based UDP server application?
A: You should use ca_udp_server_get_client when you need to retrieve information about a specific connected UDP client, such as its IP address or port, for monitoring or management purposes. It is typically called after the UDP server has been initialized and clients have connected.

Code example conf:0.90 **Q:** Can you provide a minimal C code example showing how to use ca_udp_server_get_client with caOS types?
A: u8 client_id = 0; ca_udp_srv_client_info_t client_info; bool result = ca_udp_server_get_client(c &client_info); if (result) { // Use client_info }

Parameters conf:0.95 **Q:** What are the valid ranges for the client_id parameter in ca_udp_server_get_client?
A: The client_id must be a value between 0 and UDPSRV_MAX_CLIENTS-1. Values outside this range will cause the function to return false.

Return conf:0.95 **Q:** What does it mean when ca_udp_server_get_client returns false?
A: A return value of false indicates either that the client_id is out of range (greater than or equal to UDPSRV_MAX_CLIENTS) or that the info pointer passed is NULL.

Error/Edge case conf:0.85 **Q:** What are the most common mistakes developers make when calling ca_udp_server_get_client?
A: Common mistakes include passing a client_id that is greater than or equal to UDPSRV_MAX_CLIENTS, or passing a NULL pointer for the info parameter. Both will result in the function returning false.

`ca_udp_server_send`

Header: `caos/net/inc/udp_server.h:102`
Source: `caos/net/src/udp_server.c:337:352`
GUARD: `EN_UDP_SERVER`

```
bool ca_udp_server_send(u8 client_id, const u8 *payload, u16 len)
```

Sends a UDP packet to a specific client previously registered with the UDP server.

Parametri:

Nome	Tipo	Descrizione
`client_id`	`u8`	The index of the client in the server's internal client table. Must be less than UDPSRV_MAX_CLIENTS.
`payload`	`const u8 *`	Pointer to the data buffer to be sent.
`len`	`u16`	Length of the data in bytes.

Ritorna:
Returns true if the packet was successfully queued for transmission, false if the client_id is invalid, the client is not assigned, or the transmission failed.

Note:

- This function is thread-safe as it uses a mutex to protect access to the client table. It is NOT safe to call from an ISR because it performs a mutex lock, which can cause the system to hang or trigger a kernel panic if called from an interrupt context. Ensure the UDP server has been initialized and bound using ca_udp_server_bind before attempting to send data. A common mistake is passing an uninitialized or out-of-bounds client_id, which will immediately return false.

Uso:

- This function is used to respond to clients that have previously sent data to the server. It is typically used in a request-response pattern where the server receives a packet, processes it, and then uses this function to send the reply back to the specific client identified by the index. It is usually paired with ca_udp_server_bind to set up the server and is called within the application logic after processing incoming data.

Esempio:

```
/* Assuming the server is already bound and a client is active */
void send_response_to_client(u8 cid, const u8 *data, u16 len) {
    /* Check if the client ID is within valid range before sending */
    if (cid < 10) {
        bool success = ca_udp_server_send(cid, data, len);
        if (!success) {
            /* Log error if transmission failed */
            ca_printf("Failed to send UDP packet to client %u\n", cid);
        }
    }
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_udp_server_send to send data to a UDP client?
A: You should use ca_udp_server_send when you need to send a message to a specific UDP client that has been registered with the UDP server. It is typically called after the UDP server has been initialized and a client has connected and been assigned an ID.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_udp_server_send in C with caOS types?
A: u8 client_id = 0; const u8 payload[] = {0x01, 0x02, 0x03}; u16 len = 3; bool success = ca_udp_server_send(client_id, payload, len); if (success) { // Message sent successfully } else { // Handle send failure }

Parameters conf:0.95 **Q:** What are the valid ranges for client_id and payload in ca_udp_server_send?
A: The client_id must be between 0 and UDPSRV_MAX_CLIENTS-1. Values outside this range will cause the function to return false. The payload pointer must not be NULL, and the len parameter must be greater than 0 for a successful send.

Return conf:0.95 **Q:** What does it mean when ca_udp_server_send returns false?
A: A return value of false indicates that the message was not sent. This can happen if the client_id is invalid, the client is not registered or active, or if the UDP server has not been initialized with a valid port.

Error/Edge case conf:0.90 **Q:** What are common mistakes when calling ca_udp_server_send?
A: Common mistakes include passing a client_id outside the valid range, passing a NULL payload pointer, calling the function before initializing the UDP server, or attempting to send a message with a length of 0.

Behavior conf:0.90 **Q:** Is ca_udp_server_send blocking or thread-safe, and can it be called from an ISR?
A: ca_udp_server_send is not strictly blocking but uses a mutex, so it may wait for access if another thread is using the server. It is thread-safe and can be called from

multiple threads. However, it is not ISR-safe and should not be called from an ISR.

---

ca_udp_server_set_local_ip

Header: caos/net/inc/udp_server.h:117
GUARD: EN_UDP_SERVER

```
static inline void ca_udp_server_set_local_ip(ca_ipv4_t ip)
```

Updates the local IP address configuration for the UDP server module.

Parametri:

Nome	Tipo	Descrizione
ip	ca_ipv4_t	A structure containing the new IPv4 address to be assigned to the UDP server. Ensure the address is valid and formatted correctly before passing.

Ritorna:
void

Note:

- This function is a non-blocking, inline operation that directly updates the internal configuration structure of the UDP server. It is not thread-safe by itself; if multiple tasks attempt to modify network settings simultaneously, you must ensure external synchronization. It is safe to call from an ISR if the underlying memory access is atomic, but generally, network configuration changes should be performed in a task context. A common mistake is calling this before the UDP server has been properly initialized, which may lead to the configuration being overwritten or ignored.

Uso:

- This function is typically used during the network initialization sequence, specifically after a DHCP lease has been successfully acquired or a static IP has been assigned. It is usually paired with ca_net_proto_set_local_ip to update the global network stack and ca_arp_service_update_local_ip to ensure the ARP table reflects the new address. It is often wrapped in an EVAL_UDP_SRV macro to ensure the operation only executes if the UDP server module is enabled in the project configuration.

Esempio:

```
/* Assuming 'ip' is a valid ca_ipv4_t structure obtained from DHCP */

// Update the global network protocol stack with the new IP
ca_net_proto_set_local_ip(ip);

// Update the UDP server configuration specifically
ca_udp_server_set_local_ip(ip);

// Update the ARP service to handle requests for the new IP
ca_arp_service_update_local_ip(ip);

// Notify the user via the system console
ca_stdout_printf_n("UDP Server IP updated to: %u.%u.%u.%u",
    ip.v[0], ip.v[1], ip.v[2], ip.v[3]);
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_udp_server_set_local_ip in my network initialization sequence?
A: This function should be called after the UDP server has been properly initialized. It is typically used after a DHCP lease is acquired or a static IP is assigned, and it is recommended to pair it with ca_net_proto_set_local_ip and ca_arp_service_update_local_ip to ensure consistency across the network stack.

Code example conf:0.95 **Q:** How do I implement a basic update of the UDP server IP address using caOS types?
A: You should wrap the call in the EVAL_UDP_SRV macro to ensure the module is enabled. Example: { ca_ipv4_t new_ip; new_ip.addr = 0xC0A8000A; EVAL_UDP_SRV(ca_udp_serve }

Parameters conf:1.00 **Q:** What are the requirements for the ca_ipv4_t ip parameter passed to ca_udp_server_set_local_ip?
A: The parameter must be an ca_ipv4_t structure containing the new IPv4 address. You must ensure the address is valid and formatted correctly before passing it, as the function performs a direct, non-blocking update to the internal configuration structure.

`ca_udp_server_start`

Header: `caos/net/inc/udp_server.h:89`
Source: `caos/net/src/udp_server.c:301:329`
GUARD: `EN_UDP_SERVER`

```
1 bool ca_udp_server_start(const ca_udp_server_cfg_t *cfg)
```

Initializes and launches the UDP server background tasks based on the provided configuration.

Parametri:

Nome	Tipo	Descrizione
`cfg`	`const ca_udp_server_cfg_t *`	Pointer to a configuration structure. Must contain a valid callback function (on_rx) and a non-zero number of clients not exceeding UDPSRV_MAX_CLIENTS.

Ritorna:
Returns true if the server was successfully initialized and tasks were created; returns false if the configuration is invalid or NULL.

Note:

- This function is not thread-safe and must be called during system initialization, typically within ca_os_main, before the scheduler starts running tasks. It performs internal memory initialization for mutexes and semaphores for each client slot; therefore, it must not be called more than once. It is not callable from an ISR. A common mistake is passing a NULL pointer or a configuration where max_clients exceeds the hardcoded system limit, which will cause the function to fail silently by returning false.

Uso:

- This function is used to set up the network infrastructure for UDP communication. It is typically called in the main initialization sequence alongside other network services like ca_arp_service_start or ca_dhcp_service_start. Once called, it spawns internal worker tasks that handle incoming UDP packets asynchronously. It should be invoked before any network-dependent tasks are created via ca_os_job to ensure the server is ready to process traffic.

Esempio:

```
/* Define the server configuration structure */
ca_udp_server_cfg_t srv_cfg = {
    .on_rx = my_udp_rx_callback,
    .max_clients = 2
};

void ca_os_main(void) {
    /* Initialize network services before starting tasks */
    ca_arp_service_start();

    /* Start the UDP server; check return value for safety */
    if (ca_udp_server_start(&srv_cfg)) {
        /* Server started successfully, proceed to launch application tasks */
        ca_os_job("app_task", CA_TH_LEVEL3, my_app_task, 0, STACK_SMALL,
    CA_JOB_STD, CA_FAULT_RESTART_THREAD);
    } else {
        /* Handle initialization failure */
        while(1) { /* Error: could not start UDP server */ }
    }
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_udp_server_start() in my caOS application?
A: You should call ca_udp_server_start() after initializing the caOS RTOS and setting up a valid UDP server configuration. It is typically used when you need to receive UDP packets from remote clients and process them using a callback function. The function is not blocking, so it returns immediately after initializing the server threads.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_udp_server_start() with caOS types?
A:

```
ca_udp_server_cfg_t cfg;
cfg.on_rx = my_udp_callback;
cfg.max_clients = 5;
bool success = ca_udp_server_start(&cfg);
```

This example initializes a UDP server configuration with a callback function and a maximum of 5 clients, then starts the server.

Parameters conf:0.90 **Q:** What does the max_clients parameter in ca_udp_server_start() control and what are valid values?
A: The max_clients parameter specifies the maximum number of concurrent UDP clients the server can handle. Valid values are integers between 1 and UDPSRV_MAX_CLIENTS (inclusive). If set to 0 or greater than UDPSRV_MAX_CLIENTS, the function will return false.

Return conf:0.95 **Q:** What does it mean when ca_udp_server_start() returns false?
A: A return value of false indicates that the UDP server failed to start. This happens when the configuration is invalid, such as passing a NULL pointer for cfg, having on_rx set to NULL, or setting max_clients to 0 or a value exceeding UDPSRV_MAX_CLIENTS.

Error/Edge case conf:0.90 **Q:** What are common mistakes when calling ca_udp_server_start()?
A: Common mistakes include passing a NULL pointer for the cfg parameter, not initializing the on_rx callback function, setting max_clients to 0 or a value greater than UDPSRV_MAX_CLIENTS, and calling the function before the RTOS is initialized. These errors will cause the function to return false.

Behavior conf:0.90 **Q:** Is ca_udp_server_start() thread-safe and can it be called from an ISR?
A: No, ca_udp_server_start() is not thread-safe and must not be called from multiple threads simultaneously. It also cannot be called from an ISR (Interrupt Service Rou-

tine). The function is not blocking and returns immediately after initializing the server structures and creating worker threads.

---

ca_usb_cdc_connected

Header: caos/usb/inc/usb_cdc.h:77
Source: caos/usb/src/usb_cdc.c:274:277
GUARD: EN_USB_CDC

```
bool ca_usb_cdc_connected(void)
```

Checks if the USB CDC virtual serial port is currently connected to a host.

Ritorna:
Returns true if the DTR (Data Terminal Ready) signal is asserted by the host, indicating a terminal or application is listening; returns false otherwise.

Note:

- This function is non-blocking and thread-safe as it simply reads a status flag updated by the USB interrupt service routine. It is safe to call from any context, including ISRs, because it performs a simple memory read. The most common mistake is assuming that 'connected' means the USB cable is physically plugged in; it specifically checks if the host software has opened the virtual COM port and set the DTR line. If you attempt to send data via ca_usb_cdc_write while this returns false, the data may be silently dropped or lost, so always check this status before initiating a transmission.

Uso:

- This function is typically used as a guard clause before attempting to send logs or data over USB to avoid wasting CPU cycles or memory on data that has nowhere to go. It is often paired with ca_usb_cdc_write to ensure the transmission is valid, or with ca_usb_cdc_wait_connected when the application must block until a user opens the terminal. In a typical sequence, you would initialize the USB stack, wait for connection, and then periodically check this status to handle unexpected disconnections gracefully.

Esempio:

```
/* Check if the USB CDC terminal is ready before sending data */
if (ca_usb_cdc_connected()) {
    /* Prepare a message buffer using ca_memory_allocate */
    /* Assume 'msg' is a valid pointer to a message structure */
    if (!ca_usb_cdc_write(msg)) {
        /* Handle write failure if necessary */
    }
} else {
    /* Terminal is not connected, skip transmission to save resources */
    /* Optionally wait for connection if the task is not time-critical */
    /* ca_usb_cdc_wait_connected(1000); // Wait up to 1 second */
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_cdc_connected() in my embedded application?
A: You should call ca_usb_cdc_connected() before attempting to send data over USB CDC to ensure the host is connected. This function is useful for avoiding data loss or undefined behavior that can occur when trying to transmit data without an active USB connection.

Code example conf:0.90 **Q:** Can you show a minimal C example using ca_usb_cdc_connected() with caOS types?
A:

```c
u8 send_data_if_connected(void) {
    if (ca_usb_cdc_connected()) {
        // Send data here
        return 1;
    }
    return 0;
}
```

Return conf:0.90 **Q:** What does it mean when ca_usb_cdc_connected() returns false?
A: When ca_usb_cdc_connected() returns false, it means the USB CDC device is not connected to a host computer. This typically happens when the USB cable is unplugged or the host has not yet enumerated the device. Attempting to send data in this state may result in data loss or undefined behavior.

HW differences conf:0.85 **Q:** Are there any differences in how ca_usb_cdc_connected() is implemented across different STM32 families?
A: No, there are no differences in the implementation of ca_usb_cdc_connected() across STM32 families (f1xx, f4xx, f7xx, h5xx, h7xx). All implementations simply call tud_cdc_connected() which is a TinyUSB function, indicating that the underlying USB stack is consistent across these families.

`ca_usb_cdc_get_line`

Header: `caos/usb/inc/usb_cdc.h:82`
Source: `caos/usb/src/usb_cdc.c:290:293`
GUARD: `EN_USB_CDC`

```c
const ca_usb_cdc_line_t *ca_usb_cdc_get_line(void)
```

Retrieves a pointer to the static USB CDC line configuration structure.

Ritorna:
Returns a constant pointer to the internal ca_usb_cdc_line_t structure. This pointer is never NULL as it points to a statically allocated object.

Note:

- This function is non-blocking and thread-safe because it simply returns the address of a pre-allocated static variable. It is safe to call from both tasks and ISRs. The primary precondition is that the USB CDC subsystem must have been initialized, otherwise the returned structure may contain default or uninitialized values. A common mistake is attempting to modify the fields of the returned structure directly; since it is a 'const' pointer, you should treat the configuration as read-only to avoid undefined behavior in the USB stack.

Uso:

- This function is typically used to inspect the current state of the USB CDC line (such as baud rate, parity, or stop bits) after a connection has been established. It is often paired with ca_usb_cdc_connected or ca_usb_cdc_wait_connected to ensure the line is active before reading its parameters. Developers use this to synchronize application-level serial settings with the USB host's requirements.

Esempio:

```c
/* Check if USB CDC is connected before accessing line settings */
if (ca_usb_cdc_connected()) {
    const ca_usb_cdc_line_t *line = ca_usb_cdc_get_line();

    /* Safely read the current line configuration */
    ca_printf("Current Baudrate: %lu\n", line->dwDTERate);
} else {
    /* Wait for connection if not ready */
    if (ca_usb_cdc_wait_connected()) {
        const ca_usb_cdc_line_t *line = ca_usb_cdc_get_line();
        ca_printf("Connected! Baudrate: %lu\n", line->dwDTERate);
    } else {
        ca_printf("USB CDC connection timeout.\n");
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should a developer call ca_usb_cdc_get_line() and why would they need to read the CDC configuration parameters?
A: A developer should call ca_usb_cdc_get_line() when they need to read the current USB CDC serial communication settings such as baudrate, parity, and stop bits. This function is useful for debugging or dynamically adapting application behavior based on the host's CDC configuration. Since it is non-blocking and thread-safe, it can be safely called from ISRs or task contexts without risk of data corruption or delays.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_cdc_get_line() with caOS types?
A: u32 baudrate; const ca_usb_cdc_line_t *line = ca_usb_cdc_get_line(); if (line != NULL) { baudrate = line->baudrate; // Use baudrate for further processing } else { // Handle error: CDC not initialized or not available }

Return conf:0.90 **Q:** What does it mean when ca_usb_cdc_get_line() returns NULL, and what could cause this failure?
A: When ca_usb_cdc_get_line() returns NULL, it indicates that the USB CDC module is either not initialized or not active. This can happen if the USB CDC driver has not been set up properly or if the USB peripheral is not enabled. The function does not indicate a runtime error but rather a configuration or initialization issue. The returned pointer points to a global shared variable, so it should not be modified directly.

`ca_usb_cdc_wait_connected`

Header: `caos/usb/inc/usb_cdc.h:79`
Source: `caos/usb/src/usb_cdc.c:279:288`
GUARD: `EN_USB_CDC`

```c
bool ca_usb_cdc_wait_connected(u32 timeout_ms)
```

Blocks the current task until a USB CDC connection is established or the timeout expires.

Parametri:

Nome	Tipo	Descrizione
`timeout_ms`	`u32`	Maximum time in milliseconds to wait for the DTR signal. Use 0 for no timeout (infinite wait) or a specific duration.

Ritorna:
Returns true if the USB CDC connection (DTR signal) is detected within the timeout period, otherwise returns false.

Note:

- This function is a blocking call that yields execution to other tasks via ca_os_sleep(50) while waiting. It is NOT thread-safe for concurrent calls on the same resource and must NEVER be called from an ISR (Interrupt Service Routine) because it contains blocking logic. The most common beginner mistake is calling this function inside a high-priority task without considering that it will halt that task's execution for up to the specified timeout duration, potentially starving other processes.

Uso:

- This function is typically used at the start of a task that requires a USB terminal connection to function, such as a logging or network configuration task. It is often paired with ca_usb_cdc_write to send data only after confirming the host is ready to receive. By waiting for the connection, you prevent data loss that occurs if the device attempts to transmit before the USB stack is fully enumerated and the terminal application has asserted the DTR line.

Esempio:

```
static u32 task_usb_logger(u32 arg, u32 arg2) {
    (void)arg; (void)arg2;

    // Wait up to 5 seconds for the PC to open the serial terminal
    if (ca_usb_cdc_wait_connected(5000)) {
        ca_stdout_printf_n("USB CDC connected, starting logger...");
        ca_usb_cdc_write("System Ready\n", 13);
    } else {
        // Handle case where user never connected the USB cable
        ca_stdout_printf_n("USB connection timeout.");
    }

    while (1) {
        // Perform periodic tasks
        ca_os_sleep(1000);
    }
}
```

Q&A — fine-tuning review

5/5 pairs · qwen3-coder:latest

Usage conf:0.95 **Q:** When should I call ca_usb_cdc_wait_connected() in my caOS application?
A: You should call ca_usb_cdc_wait_connected() after initializing the USB CDC driver to ensure the host (e.g., PC) is connected before attempting to send serial data. This is useful for synchronizing serial output with the host connection, preventing data loss or undefined behavior.

Code example conf:0.90 **Q:** Can you provide a minimal C example using ca_usb_cdc_wait_connected() with caOS types?
A:

```
u32 timeout = 5000;
if (ca_usb_cdc_wait_connected(timeout)) {
    ca_usb_cdc_printf("USB connected\n");
} else {
    ca_usb_cdc_printf("USB connection timeout\n");
}
```

Parameters conf:0.90 **Q:** What does the timeout_ms parameter in ca_usb_cdc_wait_connected() control, and what are valid values?
A: The timeout_ms parameter specifies the maximum time in milliseconds to wait for USB CDC connection. Valid values are any positive u32 value, or 0 to indicate non-blocking behavior (though the function will still block for at least 10ms per iteration).

Return conf:0.95 **Q:** What do the return values of ca_usb_cdc_wait_connected() indicate, and what causes it to return false?
A: The function returns true if the USB CDC device is connected, and false if the timeout expires without a connection. A false return is caused by the timeout_ms elapsing before tud_cdc_connected() returns true.

HW differences conf:0.85 **Q:** Are there any hardware differences in how ca_usb_cdc_wait_connected() is implemented across different STM32 families?
A: No, the implementation of ca_usb_cdc_wait_connected() is consistent across all supported STM32 families (f1xx, f4xx, f7xx, h5xx, h7xx). Each uses the same logic involving tud_task() and ca_os_sleep(10), checking tud_cdc_connected() in a loop until either connection occurs or timeout expires.

`ca_usb_cdc_write`

Header: `caos/usb/inc/usb_cdc.h:74`
Source: `caos/usb/src/usb_cdc.c:268:272`
GUARD: `EN_USB_CDC`

```
bool ca_usb_cdc_write(p_str message)
```

Sends a data buffer over the USB CDC virtual serial port.

Parametri:

Nome	Tipo	Descrizione
`message`	`p_str`	A pointer to a structure containing the data buffer (data) and its length (size). Must be a valid, non-NULL pointer.

Ritorna:
Returns true if the data was successfully queued for transmission, false otherwise (e.g., USB not connected, buffer overflow, or hardware error).

Note:

- This function is a wrapper that handles the low-level USB endpoint addressing for CDC communication. It is generally non-blocking, meaning it queues the data for the USB peripheral to send and returns immediately. It is not intended to be called from an ISR (Interrupt Service Routine) unless explicitly documented as thread-safe in your specific hardware abstraction layer. A common beginner mistake is calling this function before the USB host has initialized the connection, which will result in a false return value; always verify the connection status first.

Uso:

- This function is used to send telemetry, logs, or command responses to a connected PC terminal. It is typically used in a sequence: first, check if the USB CDC interface is active using ca_usb_cdc_connected(), then prepare the data structure, and finally call ca_usb_cdc_write(). It is often paired with a buffer management strategy to ensure that data is not lost if the host is not reading fast enough.

Esempio:

```
/* Example: Sending a status message to the USB host */
#include "ca_os.h"

void send_status_update(void) {
    /* Define a static message structure */
```

```
    static const char my_msg[] = "System Ready\r\n";
    p_str msg_ptr;
    msg_ptr.data = (u8*)my_msg;
    msg_ptr.size = sizeof(my_msg) - 1;

    /* Check if the USB host has opened the terminal */
    if (ca_usb_cdc_connected()) {
        /* Attempt to send the message */
        if (!ca_usb_cdc_write(&msg_ptr)) {
            /* Handle error: log to internal system or retry later */
            /* Use ca_log_log if available or handle locally */
        }
    } else {
        /* USB not connected, do nothing or wait */
    }
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_usb_cdc_write() in my caOS application?

A: You should use ca_usb_cdc_write() when you need to send data over USB CDC (Communication Device Class) interface in a blocking manner. It's typically used for logging, debugging, or communication with a host PC. The function is ideal when you require guaranteed delivery of the message before proceeding, as it blocks until the data is accepted for transmission or a timeout occurs.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_usb_cdc_write() with caOS types?

A:

```
#include "caos.h"

void send_hello(void) {
    cstr msg;
    u8 data[] = "Hello USB!";
    msg.data = data;
    msg.size = 10;
    u16 bytes_written = ca_usb_cdc_write(&msg);
    if (bytes_written == 0) {
        // Handle error
    }
}
```

Parameters conf:0.95 **Q:** What does the msg parameter in ca_usb_cdc_write() represent and what are valid values?

A: The msg parameter is a pointer to a cstr structure containing the data to be sent. It must be a valid pointer to a cstr structure, not NULL. The cstr structure has a data field pointing to the actual data and a size field indicating the number of bytes to send. If msg is NULL or msg->size is 0, the function returns 0 immediately.

Return conf:0.90 **Q:** What do the return values of ca_usb_cdc_write() mean and what causes it to return 0?

A: The function returns a positive number indicating the number of bytes successfully written to the USB transmission queue. It returns 0 if the USB CDC is not connected, if the msg parameter is NULL, if msg->size is 0, or if the write operation fails. This can happen if the USB device is not properly initialized or if the underlying USB driver fails.

HW differences conf:0.85 **Q:** Are there any hardware-specific differences in how ca_usb_cdc_write() is implemented across different STM32 families?

A: No, the implementation of ca_usb_cdc_write() is consistent across all supported STM32 families (f1xx, f4xx, f7xx, h5xx, h7xx). All implementations use the same underlying TinyUSB functions tud_cdc_connected(), tud_cdc_write(), and tud_cdc_write_flush(). The function relies on the USB CDC driver provided by TinyUSB, which abstracts hard-

ware differences, so there are no register or peripheral-specific variations in the implementation.

---

ca_usb_connect

Header: caos/drivers/inc/usb.h:108
Source: caos/drivers/src/usb.c:79:83
GUARD: EN_USB

```
void ca_usb_connect(u32 usb_num)
```

Connects the specified USB peripheral to the host by enabling the D+ pull-up resistor.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral to connect. Must be less than USB_MAX_CTRL. Values outside this range are ignored.

Ritorna:
None (void).

Note:

- This function is non-blocking and performs a low-level hardware operation to signal the USB host that a device is present. It is not thread-safe in the sense that it does not use internal mutexes, so it should be called from a single management task or protected by higher-level logic. It is not intended to be called directly from an ISR, as it interacts with driver structures that may require consistent state. The most common mistake is calling this before the USB driver has been properly initialized, which will result in a silent failure because the internal operation pointer (s_ops) will be NULL.

Uso:

- This function is typically used during the USB device lifecycle management, specifically when transitioning from a disconnected or halted state to an active state. It is often paired with ca_usb_disconnect to manage the physical connection status. In a typical application, you would call this after initializing the USB stack and descriptors to allow the host to perform enumeration. It is also used in CLI commands to 'resume' USB communication after a halt or suspend event, effectively re-triggering the host's enumeration process.

Esempio:

```
/* Example: Resuming USB communication via CLI command */
#define USB_NUM 0

void handle_usb_resume_command(void) {
    /* Check if the USB peripheral is currently in a halted state */
    if (s_dev_state == USB_ST_HALTED) {
        /* Connect the USB device to the host to trigger re-enumeration */
        ca_usb_connect(USB_NUM);

        /* Update local state machine to reflect the active status */
        s_dev_state = USB_ST_IDLE;

        /* Notify the user via the system console */
        ca_printf("USB peripheral %d connected and re-enumerating...\n", USB_NUM
    );
    } else {
        ca_printf("USB is not in a halted state, cannot resume.\n");
```

```
    }
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_connect() and what is its purpose in a caOS application?
A: You should call ca_usb_connect() after initializing the USB controller to connect a USB device. It is used to enable the USB hardware driver for a specific USB controller (e.g., USB0 or USB1) so that it can communicate with connected USB devices. This function is essential for USB communication and must be called only after the USB controller has been properly initialized.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_connect() with caOS types?
A: u32 usb_num = 0; ca_usb_connect(usb_num);

Parameters conf:0.90 **Q:** What does the usb_num parameter in ca_usb_connect() represent, and what are valid values?
A: The usb_num parameter specifies which USB controller to connect. Valid values are integers from 0 up to the maximum number of USB controllers available on the STM32 chip. For example, if the chip has two USB controllers, valid values are 0 and 1. Passing an invalid value (e.g., greater than the maximum number of controllers) may lead to undefined behavior.

Return conf:0.85 **Q:** Does ca_usb_connect() return any value, and what causes it to fail?
A: ca_usb_connect() does not return any value. It is a void function. However, it can cause errors or undefined behavior if called before the USB controller is initialized or with an invalid usb_num value. The function is not designed to explicitly report failure, but improper usage may lead to system crashes or malfunction.

`ca_usb_dbg_fs_reset`

Header: `caos/drivers/inc/usb.h:171`
GUARD: `EN_USB`

```
void ca_usb_dbg_fs_reset(void)
```

Resets the internal USB Full-Speed (FS) debugging statistics and diagnostic counters to zero.

Ritorna:
void

Note:

- This function is a non-blocking utility used to clear internal diagnostic structures, such as interrupt counters, latency measurements, and setup logs. It is not thread-safe by design, meaning it should not be called while the USB stack is actively processing interrupts or updating these statistics, as it could lead to race conditions or inconsistent data. It is generally safe to call from an ISR if the hardware implementation allows, but it is primarily intended for system initialization or manual diagnostic resets. A common beginner mistake is calling this function while the USB stack is in a high-traffic state, which may cause the diagnostic data to appear corrupted or incomplete for the current session.

Uso:

- This function is typically used during the USB subsystem initialization sequence or when a user requests a manual reset of performance metrics via a CLI command. It is often paired

with 'ca_usb_dbg_fs_stat' to clear old data before starting a new measurement period. In a typical application, you would call this during the system boot phase or after a USB re-enumeration event to ensure that the statistics reflect only the current connection cycle.

Esempio:

```
/* Reset USB FS debug counters before starting a new measurement session */
ca_usb_dbg_fs_reset();

/* Perform some USB operations... */

/* Retrieve and display the fresh statistics */
ca_usb_dbg_t stats;
ca_usb_dbg_fs_stat(&stats, 0); /* Assuming index 0 for the FS controller */
ca_printf("USB FS Reset complete. Current ISR count: %u\n", stats.isr_rx_cnt);
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_usb_dbg_fs_reset in a caOS application?

A: It is typically called during the system boot phase or after a USB re-enumeration event to ensure statistics reflect the current connection cycle. It is also used when a user requests a manual reset of performance metrics via a CLI command, often paired with ca_usb_dbg_fs_stat to clear old data before starting a new measurement period.

Code example conf:1.00 **Q:** Provide a minimal example of how to reset USB debug statistics in caOS.

A: To reset the statistics, simply call the function directly. Example: void reset_usb_metrics(void) { ca_usb_dbg_fs_reset(); }

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_usb_dbg_fs_reset and why should it be avoided?

A: A common mistake is calling this function while the USB stack is in a high-traffic state. Because the function is not thread-safe, calling it while the USB stack is actively processing interrupts or updating statistics can lead to race conditions, resulting in corrupted or incomplete diagnostic data for the current session.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_dbg_fs_reset differ across STM32 families?

A: Implementations vary significantly: the f1xx family provides an empty function if EN_USB_DBG is enabled; f4xx, f7xx, h5xx, and u5xx families reset a global usb_dbg_t structure (and s_setup_cnt for f4xx); the h7xx family performs a complex reset of multiple arrays including latency, interrupt timing, and endpoint-specific diagnostic counters for two USB instances.

`ca_usb_dbg_fs_stat`

Header: `caos/drivers/inc/usb.h:170`
GUARD: `EN_USB`

```
void ca_usb_dbg_fs_stat(ca_usb_dbg_t *out, u32 usb_num)
```

Captures a snapshot of internal USB Full-Speed peripheral diagnostic counters and status flags.

Parametri:

Nome	Tipo	Descrizione
out	ca_usb_dbg_t *	Pointer to a structure where the diagnostic data will be copied. Must not be NULL.
usb_num	u32	The index of the USB peripheral to query. Valid values depend on the MCU (usually 0 or 1).

Ritorna:
None (void). If 'out' is NULL or 'usb_num' is out of range, the function returns immediately without modifying memory.

Note:

- This function is non-blocking and thread-safe in the sense that it performs a read-only snapshot of volatile diagnostic structures. It is safe to call from an ISR, as it does not perform any complex synchronization or blocking operations. The primary purpose is to provide visibility into USB stack performance, such as endpoint transfer counts, latency, and error flags like buffer overflows. A common beginner mistake is to assume this function resets the counters; it does not. To clear the statistics, you must explicitly call ca_usb_dbg_fs_reset() before or after the snapshot.

Uso:

- This function is typically used in diagnostic tasks or CLI commands to monitor USB health. It is often paired with ca_usb_dbg_fs_reset() to measure statistics over a specific time interval. Developers use this to debug enumeration issues, NAK-heavy traffic, or dropped packets by comparing the 'out' structure values against expected traffic patterns.

Esempio:

```
ca_usb_dbg_t usb_stats;

// Reset counters to start a fresh measurement window
ca_usb_dbg_fs_reset();

// Perform some USB operations...

// Capture the current state of USB peripheral 0
ca_usb_dbg_fs_stat(&usb_stats, 0U);

// Print the number of setup packets received for debugging
ca_printf("Setup packets received: %u\n", usb_stats.setup);
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_usb_dbg_fs_stat in my caOS application?
A: You should use it in diagnostic tasks or CLI commands to monitor USB health. It is particularly useful for debugging enumeration issues, NAK-heavy traffic, or dropped packets by comparing the captured statistics against expected traffic patterns.

Code example conf:1.00 **Q:** Provide a minimal C example to capture USB statistics.
A: ca_usb_dbg_t stats; ca_usb_dbg_fs_stat(&stats, 0U);

Parameters conf:1.00 **Q:** What are the requirements for the 'out' and 'usb_num' parameters?
A: 'out' must be a non-NULL pointer to a ca_usb_dbg_t structure where data will be copied. 'usb_num' is the index of the USB peripheral; valid values depend on the MCU (e.g., 0 or 1 for H7xx). If 'out' is NULL or 'usb_num' is out of range, the function returns immediately without modifying memory.

Error/Edge case conf:1.00 **Q:** Does calling ca_usb_dbg_fs_stat reset the USB diagnostic counters?
A: No, a common beginner mistake is to assume this function resets the counters. It only performs a read-only snapshot. To clear the statistics, you must explicitly call ca_usb_dbg_fs_reset() before or after the snapshot.

Behavior conf:1.00 **Q:** Is it safe to call ca_usb_dbg_fs_stat from an interrupt service routine (ISR)?
A: Yes, the function is non-blocking and thread-safe in the sense that it performs a read-only snapshot of volatile diagnostic structures. It does not perform complex synchronization, making it safe to call from an ISR.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_dbg_fs_stat differ across MCU families?
A: Implementations vary significantly: H7xx supports two USB peripherals and tracks latency/ISR timing metrics; H5xx includes live snapshots of CHEP registers and RX/TX queue pointers; F1xx provides a minimal implementation; F7xx and H5xx include specific fields like suspension/wakeup counters, while U5xx focuses on RX buffer and write-full status.

`ca_usb_dbg_hs_reset`

Header: `caos/drivers/inc/usb.h:175`
GUARD: `EN_USB`

```
void ca_usb_dbg_hs_reset(void)
```

Resets the internal high-speed USB debug statistics and counters to zero.

Ritorna:
void

Note:

- This function is non-blocking and performs a direct memory reset of the USB debug tracking variables. It is not thread-safe; if called while the USB interrupt service routine (ISR) is actively updating these statistics, you may experience race conditions or inconsistent data. It is intended for use during system initialization or when a manual reset of the debug telemetry is required. Note that this function is only implemented for specific hardware targets (like H7xx); on other platforms, it is an empty stub, so do not rely on it to clear state across different MCU architectures.

Uso:

- This function is typically used in a diagnostic context to clear performance metrics before starting a new measurement session. It is often paired with ‘ca_usb_dbg_print‘ to ensure that the statistics displayed represent only the activity occurring after the reset. Developers should call this during the system setup phase or via a CLI command to ensure that stale data from the boot process does not pollute the runtime performance analysis.

Esempio:

```
/* Reset USB debug stats before starting a new performance test */
ca_usb_dbg_hs_reset();

/* Perform some USB operations here */

/* Print the collected statistics to the console */
ca_usb_dbg_print(0U);
```

Q&A — fine-tuning review

5/5 pairs · gemini-3.1-flash-lite

Usage conf:1.00 **Q:** When should I call ca_usb_dbg_hs_reset in my application?
A: You should call it during the system setup phase or via a CLI command before starting a new measurement session. This ensures that stale data from the boot process does not pollute your runtime performance analysis.

Code example conf:0.90 **Q:** How do I implement a simple reset and print sequence using caOS types?
A: You can reset the statistics and then print them using the following pattern: ca_usb_dbg_hs_reset(); ca_usb_dbg_print();

Error/Edge case conf:1.00 **Q:** What happens if I call ca_usb_dbg_hs_reset while the USB ISR is running?
A: The function is not thread-safe. If called while the USB interrupt service routine is actively updating statistics, you may experience race conditions or inconsistent data.

Behavior conf:1.00 **Q:** Is ca_usb_dbg_hs_reset a blocking function?
A: No, it is non-blocking and performs a direct memory reset of the USB debug tracking variables.

HW differences conf:1.00 **Q:** Does ca_usb_dbg_hs_reset work the same way on all STM32 families supported by caOS?
A: No. It is only implemented for specific hardware targets like the H7xx. On other platforms like F1xx, F7xx, H5xx, and U5xx, the function is an empty stub and will not clear any state.

`ca_usb_dbg_hs_stat`

Header: `caos/drivers/inc/usb.h:174`
GUARD: `EN_USB`

```
1 void ca_usb_dbg_hs_stat(ca_usb_dbg_t *out)
```

Retrieves internal USB High-Speed controller diagnostic statistics and performance metrics.

Parametri:

Nome	Tipo	Descrizione
`out`	`ca_usb_dbg_t *`	Pointer to a structure where the USB statistics will be copied. Must not be NULL.

Ritorna:
None. If the pointer is NULL, the function returns immediately without performing any operations.

Note:

- This function is non-blocking and thread-safe in the sense that it performs a memory copy of internal diagnostic buffers. It is safe to call from an ISR, though it is primarily intended for diagnostic tasks or CLI commands. The function relies on internal USB debug counters that must be enabled via the EN_USB_DBG configuration flag; if disabled, the function will simply zero out the provided structure. A common mistake is assuming this function resets the counters; it only reads them. To reset the statistics, you must call ca_usb_dbg_hs_reset separately.

Uso:

- This function is used to monitor the health and performance of the USB High-Speed peripheral, specifically for debugging enumeration issues or throughput bottlenecks. It is typically called within a diagnostic task or a CLI command handler to dump the state of the USB bus, such as setup packet counts, endpoint transfer counts, and latency metrics. It is usually paired with ca_usb_dbg_hs_reset to clear counters before starting a new measurement period, and it is often wrapped by the generic ca_usb_dbg_stat function to provide a unified interface across different USB hardware implementations.

Esempio:

```c
ca_usb_dbg_t usb_stats;

// Clear existing stats before starting a new measurement
ca_usb_dbg_hs_reset();

// Perform some USB operations...

// Retrieve the current statistics
ca_usb_dbg_hs_stat(&usb_stats);

// Print the number of SETUP packets received on EP0
ca_printf("Setup packets: %u\n", usb_stats.setup);

// Check if the device is currently suspended
if (usb_stats.susp) {
    ca_printf("USB is in suspend mode\n");
}
```

Q&A — fine-tuning review

7/7 pairs · gemini-3.1-flash-lite

Usage conf:1.00 **Q:** When should I use ca_usb_dbg_hs_stat in my application?

A: You should use this function to monitor the health and performance of the USB High-Speed peripheral. It is typically called within a diagnostic task or a CLI command handler to retrieve metrics like setup packet counts, endpoint transfer counts, and latency, which helps in debugging enumeration issues or throughput bottlenecks.

Code example conf:1.00 **Q:** How do I implement a simple diagnostic call to retrieve USB statistics?

A: You can retrieve the statistics by declaring a ca_usb_dbg_t structure and passing its address to the function: ca_usb_dbg_t stats; ca_usb_dbg_hs_stat(&stats);

Parameters conf:1.00 **Q:** What are the requirements for the 'out' parameter in ca_usb_dbg_hs_stat?

A: The 'out' parameter must be a pointer to a ca_usb_dbg_t structure. It must not be NULL. If a NULL pointer is passed, the function returns immediately without performing any operations.

Return conf:1.00 **Q:** What does the function return, and how do I check for errors?

A: The function returns void. There is no explicit error return value; however, if the EN_USB_DBG configuration flag is disabled, the function will simply zero out the provided structure instead of populating it with diagnostic data.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_usb_dbg_hs_stat to track USB performance?

A: A common mistake is assuming that calling ca_usb_dbg_hs_stat resets the internal counters. It only reads them. To clear the statistics for a new measurement period, you must explicitly call ca_usb_dbg_hs_reset.

Behavior conf:1.00 **Q:** Is ca_usb_dbg_hs_stat safe to call from an interrupt service routine?

A: Yes, the function is non-blocking and thread-safe in the sense that it performs a memory copy of internal diagnostic buffers, making it safe to call from an ISR.

HW differences conf:1.00 **Q:** Are there differences in how ca_usb_dbg_hs_stat behaves across different STM32 families?

A: Yes. On the H7xx family, the function performs a detailed copy of internal event buffers (g_evt) and latency metrics (lat_sum, lat_max, etc.). On the F1xx, F7xx, H5xx, and U5xx families, the function is currently implemented to simply zero out the provided structure if EN_USB_DBG is enabled.

ca_usb_dbg_print

Header: caos/drivers/inc/usb.h:181
Source: caos/usb/src/usb_mgmt.c:433:453
GUARD: EN_USB

```
void ca_usb_dbg_print(u32 usb_num)
```

Prints a detailed diagnostic report of the USB peripheral state to the system console.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral to diagnose. Must be a valid peripheral ID supported by the hardware (e.g., 0 for FS, 1 for HS).

Ritorna:
void

Note:

- This function is a diagnostic tool and is not intended for high-frequency use in production loops. It is not thread-safe if multiple tasks attempt to print to the console simultaneously, though it relies on ca_stdout_printf_n which handles output buffering. It must not be called from an ISR because it performs significant string formatting and console output operations, which are blocking and time-consuming. Ensure the USB peripheral is initialized before calling this, otherwise, the internal status structure will contain garbage data.

Uso:

- Used primarily during development or troubleshooting to verify USB enumeration, endpoint activity, and interrupt performance. It is typically paired with CLI handlers to allow developers to dump the state of the USB stack on demand. In power management scenarios, it is used to verify that the USB peripheral has correctly resumed or re-enumerated after a low-power state transition by comparing the output before and after the sleep period.

Esempio:

```
/* Example: CLI command handler to dump USB status */
static bool usb_dbg_cli_handler(c_str *pcmd) {
    const char *p = ca_skip_sp((*pcmd)->data);
    /* Check if user typed 'usbdbg' */
    if (ca_strncmp(p, "usbdbg", 6) == 0) {
        /* Get the active USB peripheral number */
        u32 usb_id = ca_usb_dev_mng_get_num();
        /* Print diagnostic info to console */
        ca_usb_dbg_print(usb_id);
        return true;
    }
    return false;
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use the ca_usb_dbg_print function in my caOS project?
A: It is primarily used during development or troubleshooting to verify USB enumeration, endpoint activity, and interrupt performance. It is also useful in power management scenarios to verify that the USB peripheral has correctly resumed or re-enumerated after a low-power state transition.

Code example conf:1.00 **Q:** Provide a minimal example of how to call ca_usb_dbg_print for the FS USB peripheral.
A: u32 usb_id = 0; ca_usb_dbg_print(usb_id);

Parameters conf:1.00 **Q:** What does the usb_num parameter represent and what are valid values?
A: The usb_num parameter is the index of the USB peripheral to diagnose. It must be a valid peripheral ID supported by the hardware, such as 0 for FS (Full Speed) or 1 for HS (High Speed).

Error/Edge case conf:1.00 **Q:** What happens if I call ca_usb_dbg_print before initializing the USB peripheral?
A: If the USB peripheral is not initialized before calling this function, the internal status structure will contain garbage data, leading to an inaccurate diagnostic report.

Behavior conf:1.00 **Q:** Is ca_usb_dbg_print safe to call from an Interrupt Service Routine (ISR) or in a multi-threaded environment?
A: No, it must not be called from an ISR because it performs significant, time-consuming, and blocking string formatting and console output operations. Additionally, it is not thread-safe if multiple tasks attempt to print to the console simultaneously.

`ca_usb_dbg_reset`

Header: `caos/drivers/inc/usb.h:179`
Source: `caos/usb/src/usb_mgmt.c:423:431`
GUARD: `EN_USB`

```
void ca_usb_dbg_reset(void)
```

Resets the internal USB debug counters and statistics for all enabled USB controllers.

Ritorna:
void

Note:

- This function is a wrapper that triggers a reset of the internal diagnostic counters for High-Speed (HS) and Full-Speed (FS) USB controllers, depending on the build configuration. It is not thread-safe in the sense that it modifies global state; if called while another task is reading statistics, the data might be inconsistent. It is generally safe to call from a task context, but you should avoid calling it from an ISR unless the underlying hardware-specific reset functions are explicitly documented as ISR-safe. The most common mistake is assuming this resets the USB hardware connection itself; it only clears the software-level debug counters used for performance monitoring.

Uso:

- This function is typically used during system maintenance or debugging sessions to clear accumulated statistics, such as interrupt counts or error flags, before starting a new test cycle. It is often paired with 'ca_usb_dbg_stat' to capture a baseline, followed by a period of USB activity, and then another 'ca_usb_dbg_stat' to analyze the delta. In a CLI environment, it is triggered by a user command to reset the performance metrics without requiring a full system reboot.

Esempio:

```
/* Example: Resetting USB debug counters via a CLI command */
#include "ca_os.h"

```

```c
void handle_usb_debug_command(char *p) {
    /* Check if the user requested a reset of the debug counters */
    if (ca_strncmp(p, "dbg reset", 9) == 0) {
        ca_usb_dbg_reset();
        /* Notify the user that the counters have been cleared */
        ca_printf("USB debug counters have been reset to zero.\n");
    } else if (ca_strncmp(p, "dbg stat", 8) == 0) {
        /* Retrieve and display current stats using ca_usb_dbg_stat */
        /* Note: ca_usb_dbg_stat is the standard way to read the counters */
        ca_printf("Displaying current USB statistics...\n");
    }
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_dbg_reset() and what is its purpose in a caOS project?
A: You should call ca_usb_dbg_reset() during debugging sessions to reset USB debug counters to zero. It is used to clear performance and activity statistics related to USB operations, which helps in analyzing USB behavior during development. The function is intended for debugging only and must not be used in production code.

Code example conf:0.90 **Q:** Can you provide a minimal C example showing how to use ca_usb_dbg_reset() with caOS types?
A:

```c
#include "caos.h"

void example_function(void)
{
    ca_usb_dbg_reset();
}
```

Error/Edge case conf:0.90 **Q:** What are the common mistakes or edge cases when using ca_usb_dbg_reset()?
A: A common mistake is calling ca_usb_dbg_reset() from an ISR if the debug counters are shared, as it may cause concurrency issues or data corruption. Additionally, the function is not thread-safe and should only be called when the system is in a stable state. It is also not meant for use in production code and should only be used during debugging.

Behavior conf:0.90 **Q:** Is ca_usb_dbg_reset() blocking or non-blocking, and is it safe to call from an ISR or in a multi-threaded environment?
A: ca_usb_dbg_reset() is a blocking function and is not thread-safe. It should not be called from an ISR if the debug counters are shared, as it could lead to race conditions or corrupted data. It must be called only when the system is in a stable state and is intended for single-threaded debugging scenarios.

HW differences conf:0.85 **Q:** How does ca_usb_dbg_reset() differ between F4xx, H7xx, and U5xx MCU families in caOS?
A: In F4xx, ca_usb_dbg_reset() resets only the global debug structure and a setup counter. In H7xx, it resets multiple debug structures and various counters for both USB instances (0 and 1), including ISR RX, IAT, and latency counters per endpoint. U5xx uses a simpler reset of the global debug structure similar to F4xx but without additional counters.

`ca_usb_dbg_stat`

Header: `caos/drivers/inc/usb.h:178`
Source: `caos/usb/src/usb_mgmt.c:411:421`
GUARD: `EN_USB`

```
void ca_usb_dbg_stat(ca_usb_dbg_t *out, u32 usb_num)
```

Retrieves real-time diagnostic statistics from the specified USB controller hardware.

Parametri:

Nome	Tipo	Descrizione
out	ca_usb_dbg_t *	Pointer to a structure where the USB diagnostic data will be stored. Must not be NULL.
usb_num	u32	The index of the USB controller to query (0 for primary, 1 for secondary). Valid values depend on hardware configuration.

Ritorna:
This function returns void. If the provided pointer is NULL, the function safely does nothing (or clears the structure if supported).

Note:

- This function is a dispatcher that routes the request to the appropriate low-level driver (HS or FS) based on your system configuration. It is non-blocking and executes quickly, making it safe to call from most contexts, though it is primarily intended for CLI or monitoring tasks. It is not thread-safe in the sense that it does not lock the USB hardware; if the USB controller is undergoing a reset or heavy re-initialization, the data returned might be inconsistent. The most common beginner mistake is passing an uninitialized pointer or assuming the data is updated in real-time without considering the overhead of the USB interrupt activity it measures.

Uso:

- This function is used for system health monitoring and debugging USB communication issues. It is typically called within a CLI command handler or a background monitoring task to inspect endpoint status, interrupt counts, and latency metrics. You would typically pair this with other diagnostic tools to print the gathered data to the console, allowing you to verify if endpoints are stalled or if the interrupt service routine is processing data as expected.

Esempio:

```
void usb_monitor_task(void) {
    ca_usb_dbg_t usb_stats;
    // Retrieve stats for the first USB controller
    ca_usb_dbg_stat(&usb_stats, 0U);

    // Check if the controller has processed any RX interrupts
    if (usb_stats.isr_rx_cnt > 0U) {
        ca_printf_n("USB Controller 0 active. RX count: %lu", usb_stats.
    isr_rx_cnt);
    } else {
        ca_printf_n("USB Controller 0 idle or inactive.");
    }

    // Example of checking endpoint 1 status
    // The chep array contains bit-packed status information
    u32 ep1_status = usb_stats.chep[1];
    ca_printf_n("EP1 raw status: 0x%08lx", ep1_status);
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_dbg_stat() and what is its purpose in debugging USB issues?

A: You should call ca_usb_dbg_stat() during debugging to print detailed statistics about the USB state, including endpoint transfer counts, buffer status, and packet loss information. It helps analyze endpoint behavior and identify issues like buffer overflows or dropped packets.

Code example conf:0.90 **Q:** Can you provide a minimal C example showing how to use ca_usb_dbg_stat() with caOS types?
A:

```c
void example_usb_debug(void)
{
    // Ensure USB is initialized before calling
    ca_usb_dbg_stat(); // Prints USB debug info to stdout
}
```

Error/Edge case conf:0.90 **Q:** What are the common mistakes or error conditions when using ca_usb_dbg_stat()?
A: Common mistakes include calling the function without initializing the USB subsystem, calling it during active data transfers which may result in stale data, or ignoring the debug output that could indicate buffering issues or packet loss.

Behavior conf:0.95 **Q:** Is ca_usb_dbg_stat() blocking, ISR-safe, or thread-safe, and what are its preconditions?
A: ca_usb_dbg_stat() is a blocking function that does not return until printing is complete. It is not ISR-safe and not thread-safe. It requires the USB system to be initialized and functioning. It must not be called from an ISR.

`ca_usb_dev_mng_add`

Header: `caos/usb/inc/usb_mgmt.h:132`
Source: `caos/usb/src/usb_mgmt.c:363:376`
GUARD: `EN_USB_MGMT`

```c
bool ca_usb_dev_mng_add (const ca_usb_device_type_t *cfg)
```

Registers a new USB device configuration into the USB management system.

Parametri:

Nome	Tipo	Descrizione
`cfg`	`const ca_usb_device_type_t *`	Pointer to the USB device configuration structure. Must not be NULL, must contain valid operations, and must have a valid device type index.

Ritorna:
Returns true if the device was successfully registered, false if the configuration is invalid, the device type is already registered, or if there is an endpoint resource collision.

Note:

- This function is not thread-safe and is intended to be called during the system initialization phase before the USB stack is started. It performs a static check for endpoint (EP) collisions; if two different USB device types attempt to use the same hardware endpoint, the function will reject the second one. It is not callable from an ISR. A common mistake is attempting to add a device after calling ca_usb_dev_mng_start, which may lead to inconsistent USB enumeration states.

Uso:

- This function is part of the USB initialization sequence. It is typically used after ca_usb_dev_mng_init and before ca_usb_dev_mng_start. You use it to register specific USB classes (like CDC or custom HID) into the management array. If you need to change device configurations at runtime, you must first call ca_usb_dev_mng_remove to free the endpoint resources before adding a new configuration.

Esempio:

```c
/* Initialize USB management first */
if (ca_usb_dev_mng_init(CA_USB_SPEED_FS, 1U)) {
    /* Define and add a custom USB device configuration */
    static const ca_usb_device_type_t my_usb_cfg = { /* ... configuration data ... */ };

    if (ca_usb_dev_mng_add(&my_usb_cfg)) {
        ca_stdout_put_n("[USB] Device added successfully");
        /* Start the USB stack to allow host enumeration */
        ca_usb_dev_mng_start();
    } else {
        ca_stdout_put_n("[USB] Failed to add device: check for EP collisions");
    }
} else {
    ca_stdout_put_n("[USB] Manager init failed");
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_usb_dev_mng_add in the caOS initialization sequence?
A: It should be called during the system initialization phase, specifically after ca_usb_dev_mng_init and before ca_usb_dev_mng_start. It is intended to register specific USB classes like CDC or HID into the management system.

Code example conf:0.90 **Q:** How do I register a USB device configuration using caOS types?
A: You pass a pointer to a ca_usb_device_type_t structure to the function: ca_usb_device_type_t my_dev; bool status = ca_usb_dev_mng_add(&my_dev);

Parameters conf:1.00 **Q:** What are the requirements for the cfg parameter in ca_usb_dev_mng_add?
A: The cfg parameter must be a non-NULL pointer to a ca_usb_device_type_t structure. It must contain valid operations and a valid device type index.

Return conf:1.00 **Q:** What does a false return value from ca_usb_dev_mng_add indicate?
A: A false return indicates that the configuration is invalid, the device type is already registered, or there is an endpoint resource collision where two device types attempt to use the same hardware endpoint.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_usb_dev_mng_add?
A: A common mistake is attempting to add a device after calling ca_usb_dev_mng_start, which may lead to inconsistent USB enumeration states. Additionally, the function is not thread-safe and cannot be called from an ISR.

`ca_usb_dev_mng_cdc_cli`

Header: `caos/usb/inc/usb_cdc.h:91`
Source: `caos/usb/src/usb_cdc.c:343:358`
GUARD: `EN_USB_CDC`

```c
bool ca_usb_dev_mng_cdc_cli(void)
```

Initializes and starts the USB CDC device manager for CLI communication.

Ritorna:
Returns true if the USB device manager was successfully initialized, configured, and started; returns false if any step (init, add, or start) fails.

Note:

- This function is intended to be called during system startup, specifically within ca_os_main before the RTOS scheduler is fully operational. It is not thread-safe and must never be called from an ISR. The function performs a blocking delay (ca_os_delay_ms) to allow the USB hardware and clock tree to stabilize after the D+ pull-up is enabled. A common mistake is calling this function after the scheduler has started or inside a task, which can lead to race conditions during USB enumeration or system instability due to the blocking nature of the internal delays.

Uso:

- This function is typically used in the main initialization sequence of an embedded application to enable a USB-based Command Line Interface (CLI). It is usually paired with ca_cli_create_thread and ca_cli_set_sender to establish the full CLI environment. The sequence is: 1) Initialize system peripherals, 2) Call ca_usb_dev_mng_cdc_cli to bring up the USB stack, 3) Configure the CLI hooks, and 4) Start the RTOS scheduler.

Esempio:

```
void ca_os_main(void) {
    /* Initialize the USB CDC CLI interface */
    if (ca_usb_dev_mng_cdc_cli()) {
        /* Configure the CLI to use the USB CDC as the output stream */
        ca_cli_set_sender(STDOUT);
        /* Create the CLI task to process user commands */
        ca_cli_create_thread();
    } else {
        /* Handle initialization failure, e.g., log error or enter safe mode */
        /* ca_printf("USB CLI init failed!\r\n"); */
    }
    /* Start the RTOS scheduler */
    ca_os_run();
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_usb_dev_mng_cdc_cli in my application?
A: It should be called during the system startup sequence, specifically within ca_os_main before the RTOS scheduler is fully operational. It is typically used to enable a USB-based CLI before starting the scheduler.

Code example conf:0.90 **Q:** How do I implement the initialization sequence for the USB CLI in caOS?
A: You should initialize peripherals, call ca_usb_dev_mng_cdc_cli, configure CLI hooks, and then start the scheduler. Example: { bool status = ca_usb_dev_mng_cdc_cli(); if(status) { ca_cli_create_thread(); ca_cli_set_sender(my_sender_func); } }

Return conf:1.00 **Q:** What do the boolean return values of ca_usb_dev_mng_cdc_cli indicate?
A: The function returns true if the USB device manager was successfully initialized, configured, and started. It returns false if any of these steps (init, add, or start) fail.

Error/Edge case conf:1.00 **Q:** What are the common mistakes or risks when calling ca_usb_dev_mng_cdc_cli
A: A common mistake is calling this function after the scheduler has started or inside a task, which can lead to race conditions during USB enumeration or system instability due to the internal blocking delays.

Behavior conf:1.00 **Q:** Is ca_usb_dev_mng_cdc_cli thread-safe or ISR-safe?
A: No, it is not thread-safe and must never be called from an ISR. It performs a blocking delay (ca_os_delay_ms) to allow the USB hardware and clock tree to stabilize.

---

ca_usb_dev_mng_get_num

Header: `caos/usb/inc/usb_mgmt.h:144`
Source: `caos/usb/src/usb_mgmt.c:402:405`
GUARD: `EN_USB_MGMT`

```
u32 ca_usb_dev_mng_get_num(void)
```

Retrieves the internal identifier (index) of the currently active USB device.

Ritorna:
Returns a u32 representing the USB device index. This value is typically used as a handle for subsequent USB endpoint operations.

Note:

- This function is a simple getter for a static internal variable and is non-blocking. It is thread-safe in the sense that it performs a read operation on a variable, but it does not provide synchronization guarantees if the USB device is being reconfigured or removed simultaneously. It is safe to call from an ISR, as it does not involve any OS primitives or blocking logic. The most common mistake is assuming the returned index is valid even when the USB stack is not initialized or has been stopped; always ensure the USB subsystem is in a valid state before using this index to open endpoints.

Uso:

- This function is used as a prerequisite for almost all USB-related operations that require a device handle. In a typical lifecycle, it is called during the device configuration phase (e.g., inside an 'on_configure' callback) to obtain the index needed to open endpoints via 'ca_usb_ep_open'. It is also used in diagnostic contexts to identify which USB instance is being referenced when printing debug information or performing status checks.

Esempio:

```
/* Example: Initializing endpoints for a custom USB device */
static void custom_on_configure(const ca_usb_device_type_t *cfg) {
    /* Retrieve the current USB device index */
    u32 usb_idx = ca_usb_dev_mng_get_num();

    /* Use the index to open endpoints for data transfer */
    /* Assuming d->ep_data is a valid endpoint address from config */
    ca_usb_ep_open(usb_idx, 0x81U, 0x02U, 64U); /* Open IN endpoint */
    ca_usb_ep_open(usb_idx, 0x01U, 0x02U, 64U); /* Open OUT endpoint */

    /* Log the initialization for debugging */
    ca_printf("USB device %lu configured successfully\n", usb_idx);
}
```

Q&A — fine-tuning review

3/3 pairs · gemini-3.1-flash-lite

Usage conf:1.00 **Q:** When should I call ca_usb_dev_mng_get_num and why is it necessary?
A: You should call this function during the device configuration phase, such as within an 'on_configure' callback. It is necessary because it retrieves the internal identifier (index) required as a handle for subsequent USB operations, such as opening endpoints with ca_usb_ep_open.

Code example conf:0.90 **Q:** Provide a minimal C example showing how to retrieve the USB device index and use it to open an endpoint.
A: u32 dev_idx = ca_usb_dev_mng_get_num(); if (dev_idx != 0xFFFFFFFF) { ca_usb_ep_open(dev_idx, 0x81); }

Return conf:1.00 **Q:** What does the return value of ca_usb_dev_mng_get_num represent, and are there any risks if the USB stack is not initialized?
A: The function returns a u32 representing the index of the currently active USB device. A common mistake is assuming this index is valid when the USB stack is stopped or uninitialized; if the USB subsystem is not in a valid state, the returned index may not be usable for subsequent operations.

`ca_usb_dev_mng_init`

Header: `caos/usb/inc/usb_mgmt.h:129`
Source: `caos/usb/src/usb_mgmt.c:321:335`
GUARD: `EN_USB_MGMT`

```
bool ca_usb_dev_mng_init (ca_usb_speed_t speed, u32 usb_num)
```

Initializes the USB device management layer and prepares the hardware interface for a specific USB controller.

Parametri:

Nome	Tipo	Descrizione
`speed`	`ca_usb_speed_t`	The desired USB operating speed (e.g., CA_USB_SPEED_FS for Full Speed). Must be a valid enum value supported by the hardware.
`usb_num`	`u32`	The index of the USB peripheral to initialize (e.g., 0 or 1). Must be less than 8; values >= 8 are invalid and will cause initialization failure.

Ritorna:
Returns true if the USB management layer was successfully initialized. Returns false if the specified usb_num is already in use, if the hardware initialization fails, or if invalid parameters are provided.

Note:

- This function is not thread-safe and must be called during the system initialization phase before starting the RTOS scheduler or spawning USB-related tasks. It is strictly non-blocking and must NOT be called from an ISR, as it performs internal memory resets and hardware configuration that require a stable thread context. A common beginner mistake is calling this function multiple times without first calling a de-initialization or stop function, which will trigger the 'already in use' error. Ensure that the system clock and GPIOs associated with the USB peripheral are configured correctly before invoking this, as the underlying hardware init will fail otherwise.

Uso:

- This function is the mandatory entry point for any USB-based application in caOS. It is typically used in the following sequence: first, call ca_usb_dev_mng_init to set up the management layer; second, call ca_usb_dev_mng_add to register specific USB device classes (like CDC or HID); and finally, call ca_usb_dev_mng_start to begin the enumeration process. It is paired with ca_usb_dev_mng_add to build the device descriptor tree before the host is allowed to connect.

Esempio:

```c
/* Initialize USB peripheral 0 at Full Speed */
if (!ca_usb_dev_mng_init(CA_USB_SPEED_FS, 0U)) {
    /* Handle initialization error: check clocks or GPIO configuration */
    ca_stdout_put_n("USB Init Failed!\n");
} else {
    /* Add a device class header to the management list */
    if (!ca_usb_dev_mng_add(&my_device_header)) {
        ca_stdout_put_n("Failed to add USB device class\n");
    } else {
        /* Start the USB management process to allow host enumeration */
        ca_usb_dev_mng_start();
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_dev_mng_init in my caOS application?
A: This function must be called during the system initialization phase, specifically before starting the RTOS scheduler or spawning USB-related tasks. It serves as the mandatory entry point for USB applications, followed by ca_usb_dev_mng_add and ca_usb_dev_mng_start.

Code example conf:0.90 **Q:** Provide a minimal code snippet to initialize the USB management layer.
A: u32 usb_index = 0; bool status = ca_usb_dev_mng_init(CA_USB_SPEED_FS, usb_index); if (status) { /* Proceed to add device classes */ }

Parameters conf:1.00 **Q:** What are the constraints for the usb_num parameter?
A: The usb_num parameter represents the index of the USB peripheral. It must be a value less than 8. Any value of 8 or greater is considered invalid and will result in an initialization failure.

Return conf:1.00 **Q:** What does a false return value from ca_usb_dev_mng_init indicate?
A: A false return indicates that the initialization failed. This occurs if the specified usb_num is already in use, if the hardware initialization fails, or if invalid parameters were provided.

Error/Edge case conf:1.00 **Q:** Why does my code trigger an 'already in use' error when calling ca_usb_dev_mng_init?
A: This error occurs if you call the function multiple times without first calling a de-initialization or stop function. Additionally, ensure that system clocks and GPIOs associated with the USB peripheral are configured correctly before calling this function, as hardware initialization will fail otherwise.

`ca_usb_dev_mng_remove`

Header: `caos/usb/inc/usb_mgmt.h:135`
Source: `caos/usb/src/usb_mgmt.c:378:385`
GUARD: `EN_USB_MGMT`

```c
bool ca_usb_dev_mng_remove(ca_usb_type_t type)
```

Removes a registered USB device from the management system and frees its associated endpoint resources.

Parametri:

Nome	Tipo	Descrizione
type	ca_usb_type_t	The identifier of the USB device type to remove. Must be a valid enum value within the range (0, CA_USB_TYPE___MAX).

Ritorna:
Returns true if the device was found and successfully removed. Returns false if the type is invalid, out of range, or if no device is currently registered for that type.

Note:

- This function is not thread-safe and should be called within a controlled context where the USB management state is not being concurrently modified. It is not intended for use inside an ISR, as it performs internal management logic that assumes a stable environment. The most common mistake is attempting to remove a device that was never successfully added or has already been removed, which will result in a false return value. Ensure that any hardware-level USB activity associated with this device type is stopped or quiesced before calling this function to avoid dangling endpoint references.

Uso:

- This function is typically used during the teardown phase of a USB device lifecycle or when reconfiguring the USB stack at runtime. It is usually paired with ca_usb_dev_mng_add (not shown here but implied) to manage dynamic device registration. In a CLI or configuration task, it is used to safely unregister a specific USB class (like DFU or a custom interface) so that the endpoint mask can be updated and the resources reclaimed for other purposes.

Esempio:

```
/* Example: Removing a custom USB device via CLI command */
#include "ca_os.h"

void handle_usb_remove_command(char *p) {
    /* Check if the user requested to remove the custom USB device */
    if (ca_strncmp(p, "remove", 6) == 0) {
        /* Attempt to remove the device from the management table */
        bool success = ca_usb_dev_mng_remove(CA_USB_TYPE_CUSTOM);

        if (success) {
            ca_printf_n("[USB] Custom device removed successfully.");
        } else {
            /* This happens if the device was not present or type was invalid */
            ca_printf_n("[USB] Error: Could not remove custom device (not
   present).");
        }
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_dev_mng_remove and what is its primary purpose?
A: This function is used during the teardown phase of a USB device lifecycle or when reconfiguring the USB stack at runtime. Its purpose is to remove a registered USB device from the management system and free its associated endpoint resources, allowing the endpoint mask to be updated and resources reclaimed.

Code example conf:0.90 **Q:** How do I implement a safe removal of a USB device in caOS?
A: Ensure hardware-level activity is quiesced first, then call the function: bool success = ca_usb_dev_mng_remove(CA_USB_TYPE_DFU); if (!success) { /* handle error */ }

Parameters conf:1.00 **Q:** What are the constraints for the ca_usb_type_t parameter?
A: The parameter must be a valid enum value within the range (0, CA_USB_TYPE___MAX). Providing a value outside this range will result in the function returning false.

Return conf:1.00 **Q:** What does a false return value from ca_usb_dev_mng_remove indicate?
A: A false return indicates that the removal failed. This occurs if the provided type is invalid or out of range, or if no device is currently registered for that type. A common mistake is attempting to remove a device that was never added or has already been removed.

`ca_usb_dev_mng_start`

Header: `caos/usb/inc/usb_mgmt.h:138`
Source: `caos/usb/src/usb_mgmt.c:387:393`
GUARD: `EN_USB_MGMT`

```
bool ca_usb_dev_mng_start (void)
```

Initializes USB descriptors and enables the D+ pull-up resistor to signal device presence to the host.

Ritorna:
Always returns true, indicating the USB stack has been instructed to start.

Note:

- This function is not thread-safe and should be called during the system initialization phase or from a dedicated management task. It is strictly non-blocking, meaning it triggers the hardware connection and returns immediately; however, the actual USB enumeration by the host happens asynchronously afterward. A common beginner mistake is to attempt to send data immediately after calling this function; you must wait for the host to complete enumeration (e.g., using ca_usb_cdc_wait_connected) before attempting any communication. Ensure that all USB device descriptors and endpoints have been configured via ca_usb_dev_mng_add before invoking this start function.

Uso:

- This function is the final step in the USB initialization sequence. It is typically used after calling ca_usb_dev_mng_add to register specific device classes (like CDC or HID). Once started, the device pulls the D+ line high, which alerts the USB host that a device is connected. It is often paired with ca_usb_dev_mng_stop when the device needs to be logically disconnected from the bus, such as during a system reset or power-saving mode.

Esempio:

```
/* Initialize USB CDC device and start the stack */
if (ca_usb_dev_mng_add(&my_cdc_header)) {
    /* Start the USB stack to enable D+ pull-up */
    ca_usb_dev_mng_start();

    /* Wait for the host to enumerate the device before sending data */
    if (ca_usb_cdc_wait_connected()) {
        ca_stdout_put_n("USB Host connected and enumerated");
    } else {
        ca_stdout_put_n("USB connection timeout");
    }
} else {
    ca_stdout_put_n("Failed to add USB device");
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_dev_mng_start in my initialization sequence?
A: You should call it as the final step of the USB initialization sequence, specifically after all device descriptors and endpoints have been configured using ca_usb_dev_mng_add. It is used to signal the host that the device is present by enabling the D+ pull-up resistor.

Code example conf:0.90 **Q:** How do I correctly initialize the USB stack using caOS types?
A: You must first register your classes and then start the management stack. Example: { ca_usb_dev_mng_add(descriptor_ptr); bool status = ca_usb_dev_mng_start(); if (status) { ca_usb_cdc_wait_connected(); } }

Return conf:1.00 **Q:** What does the return value of ca_usb_dev_mng_start indicate, and what causes it to fail?
A: The function always returns true, which indicates that the USB stack has been successfully instructed to start. There are no documented failure conditions that result in a false return value.

`ca_usb_dev_mng_stop`

Header: `caos/usb/inc/usb_mgmt.h:141`
Source: `caos/usb/src/usb_mgmt.c:395:400`
GUARD: `EN_USB_MGMT`

```
bool ca_usb_dev_mng_stop (void)
```

Stops the USB device management service and disconnects the device from the host.

Ritorna:
Always returns true, indicating the stop command has been processed.

Note:

- This function is not thread-safe and should be called from a single control task to avoid race conditions with the USB state machine. It is a non-blocking operation that immediately triggers a hardware disconnect. It must only be called after the USB management system has been successfully initialized via ca_usb_dev_mng_init. A common mistake is calling this function while a data transfer is still in progress, which may lead to unexpected behavior or incomplete packets on the host side.

Uso:

- This function is typically used in command-line interfaces or system state machines to gracefully shut down USB communication. It is the counterpart to ca_usb_dev_mng_start and is often paired with it to toggle USB connectivity. In a typical lifecycle, you would call this to release the USB bus before entering a low-power mode or when reconfiguring the USB device descriptors.

Esempio:

```
/* Example: Stopping the USB service via a CLI command */
#include "ca_os.h"

void handle_usb_stop_command(char *cmd) {
    if (ca_strncmp(cmd, "stop", 4) == 0) {
        /* Stop the USB management service */
        bool success = ca_usb_dev_mng_stop();

        if (success) {
            ca_printf("USB service stopped successfully.\n");
        } else {
```

```
            ca_printf("Failed to stop USB service.\n");
        }
    }
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_dev_mng_stop in my caOS application?
A: You should call this function to gracefully shut down USB communication, such as when preparing to enter a low-power mode or when reconfiguring USB device descriptors. It is typically used in command-line interfaces or system state machines to release the USB bus.

Code example conf:0.90 **Q:** How do I implement a simple toggle for the USB service using caOS functions?
A: You can manage the USB lifecycle by calling the start and stop functions. Example: void toggle_usb(bool active) { if (active) { ca_usb_dev_mng_start(); } else { ca_usb_dev_mng_stop(); } }

Return conf:1.00 **Q:** What does the boolean return value of ca_usb_dev_mng_stop indicate, and can it fail?
A: The function always returns true, which indicates that the stop command has been processed. There are no documented failure states for the return value itself, though the function must only be called after a successful ca_usb_dev_mng_init.

`ca_usb_dfu_poll`

Header: `caos/usb/inc/usb_dfu.h:89`
Source: `caos/usb/src/usb_dfu.c:167:189`
GUARD: `EN_USB_DFU`

```
bool ca_usb_dfu_poll(u32 wait_ms)
```

Processes pending USB DFU (Device Firmware Upgrade) requests by waiting for a semaphore signal.

Parametri:

Nome	Tipo	Descrizione
`wait_ms`	`u32`	Time in milliseconds to wait for a DFU job. Use CA_WAIT_FOREVER to block indefinitely until a job arrives.

Ritorna:
Returns true if a DFU job was successfully processed, false if the timeout expired or the job type was invalid.

Note:

- This function is blocking; it uses ca_sem_timedwait internally to suspend the calling task until the USB interrupt handler signals that a new DFU block or manifest command has arrived. It is NOT thread-safe for concurrent calls and must be called from a single dedicated task. It is not callable from an ISR. A common beginner mistake is calling this function from multiple tasks or failing to provide a valid configuration pointer (s_cfg) before the USB host starts sending data, which will cause the function to return false.

Uso:

- This function is the core of the DFU update loop. It is typically used in a dedicated background task that runs in an infinite loop. The sequence is: 1) Initialize the system, 2)

Enter a while(1) loop, 3) Call ca_usb_dfu_poll with CA_WAIT_FOREVER, 4) Check the result and perform system actions like resetting the device via ca_os_reset once the update is complete. It pairs with the USB stack's interrupt-driven job posting mechanism.

Esempio:

```c
/* Dedicated task for handling DFU updates */
void dfu_task(void *arg) {
    while (1) {
        /* Wait for a DFU job from the USB host */
        if (ca_usb_dfu_poll(CA_WAIT_FOREVER)) {
            /* Job processed successfully */
            ca_printf("DFU block processed\n");
        } else {
            /* Handle error or timeout */
            ca_printf("DFU poll failed or timed out\n");
        }

        /* Check if we need to reboot after update */
        if (/* check if s_dfu_reset flag is set */ 1) {
            ca_os_sleep(1000);
            ca_os_reset();
        }
    }
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When and why should I call ca_usb_dfu_poll in my application?
A: You should call ca_usb_dfu_poll within a dedicated background task's infinite loop. It is used to process pending USB DFU requests, allowing the system to handle firmware update blocks or manifest commands sent by a USB host.

Code example conf:0.95 **Q:** Provide a minimal C code example for implementing the DFU update loop using caOS types.
A: void dfu_task(void *p) { while(1) { if(ca_usb_dfu_poll(CA_WAIT_FOREVER)) { /* Processed successfully */ } else { /* Handle timeout or error */ } } }

Parameters conf:1.00 **Q:** What does the wait_ms parameter control and what is the significance of CA_WAIT_FOREVER?
A: The wait_ms parameter specifies the time in milliseconds to wait for a DFU job. Using CA_WAIT_FOREVER allows the function to block indefinitely until a job arrives, which is the standard approach for a dedicated DFU background task.

Return conf:1.00 **Q:** What do the return values of ca_usb_dfu_poll indicate?
A: It returns true if a DFU job was successfully processed. It returns false if the specified timeout expired or if the received job type was invalid.

Error/Edge case conf:1.00 **Q:** What are the common mistakes or error conditions that cause ca_usb_dfu_poll to return false?
A: Common mistakes include failing to provide a valid configuration pointer (s_cfg) before the USB host starts sending data, or calling the function from multiple tasks simultaneously, which violates its thread-safety requirements.

Behavior conf:1.00 **Q:** Is ca_usb_dfu_poll safe to call from an ISR or multiple tasks?
A: No, it is not ISR-safe. Furthermore, it is not thread-safe for concurrent calls and must be called from a single dedicated task because it uses ca_sem_timedwait internally to suspend the calling task.

ca_usb_disconnect

Header: caos/drivers/inc/usb.h:109
Source: caos/drivers/src/usb.c:85:89
GUARD: EN_USB

```
void ca_usb_disconnect(u32 usb_num)
```

Performs a soft disconnect of the USB device by signaling the host to drop the connection.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB controller to disconnect. Must be less than USB_MAX_CTRL and correspond to an initialized controller.

Ritorna:
void. The function does not return a status code; it silently ignores invalid controller indices.

Note:

- This function is non-blocking and performs a 'soft' disconnect, meaning it pulls the D+ line low (or equivalent) to simulate a physical unplug event to the host. It is not inherently thread-safe if multiple tasks attempt to manipulate the same USB controller state simultaneously, so ensure proper synchronization if your application architecture allows concurrent access. It is generally safe to call from most contexts, but avoid calling it from high-priority ISRs if the underlying driver implementation performs complex operations or memory management. The most common beginner mistake is assuming this function physically powers down the USB peripheral; it only signals the host to stop communication, leaving the peripheral hardware in its current power state.

Uso:

- This function is typically used during system shutdown, device re-enumeration, or when the user explicitly requests a 'halt' or 'soft disconnect' via a CLI command. It is usually paired with ca_usb_connect to restore the link after a maintenance task or configuration change. In a typical lifecycle, you would call it as part of a teardown sequence (e.g., stopping the USB management service) to ensure the host does not attempt to send data to a device that is about to enter a low-power or idle state.

Esempio:

```c
/* Example: Handling a user command to halt the USB interface */
#define USB_NUM 0

void handle_usb_halt_command(void) {
    /* Check if the USB controller is currently active */
    if (ca_usb_cdc_connected(USB_NUM)) {
        /* Signal the host that the device is disconnecting */
        ca_usb_disconnect(USB_NUM);

        /* Log the action to the system console */
        ca_printf("USB controller %d has been soft-disconnected.\n", USB_NUM);
    } else {
        ca_printf("USB controller %d is already disconnected.\n", USB_NUM);
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_usb_disconnect and what is its purpose in a caOS application?
A: You should call ca_usb_disconnect when you need to physically disconnect a specific USB interface in your caOS application. This function is useful for implementing soft USB device control, such as simulating a USB unplugging event. It is intended for use in main control contexts or RTOS tasks, not from ISR, as it is a blocking and non-thread-safe function.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_disconnect with caOS types?
A: u32 usb_num = 0; ca_usb_disconnect(usb_num);

Parameters conf:0.90 **Q:** What does the usb_num parameter in ca_usb_disconnect represent and what are valid values?
A: The usb_num parameter represents the identification number of the USB interface to disconnect. It must be a valid value between 0 and the maximum number of USB interfaces available on the device. Values that are negative or greater than the maximum number of USB interfaces will cause undefined behavior.

`ca_usb_ep_clear_stall`

Header: `caos/drivers/inc/usb.h:123`
Source: `caos/drivers/src/usb.c:103:107`
GUARD: `EN_USB`

```
bool ca_usb_ep_clear_stall(u32 usb_num, u8 ep_addr)
```

Clears the STALL condition on a specific USB endpoint to resume normal data communication.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller (e.g., 0 for FS, 1 for HS). Must be less than USB_MAX_CTRL.
`ep_addr`	`u8`	The hardware address of the endpoint (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2).

Ritorna:
Returns true if the stall was successfully cleared, false if the controller index is invalid or the operation failed.

Note:

- This function is typically non-blocking and interacts directly with the USB hardware registers. It is not guaranteed to be thread-safe if called simultaneously from multiple tasks, so it should ideally be called from the USB management task or the USB ISR context. A common beginner mistake is calling this function without first verifying if the endpoint is actually stalled using ca_usb_ep_is_stalled, or failing to handle the subsequent USB protocol requirements (like sending a Zero Length Packet) after clearing the stall. Ensure the USB controller is initialized before calling this.

Uso:

- This function is used during USB enumeration or runtime when the host sends a CLEAR_FEATURE request to an endpoint. It is part of the standard USB control transfer sequence: the firmware receives a setup packet, identifies the request, calls ca_usb_ep_clear_stall to reset the endpoint's data toggle and stall bit, and then typically calls ca_usb_ep_write

to send a status response (ZLP) back to the host. It is often paired with ca_usb_ep_stall when the device needs to signal an error to the host.

Esempio:

```c
/* Example: Handling a USB CLEAR_FEATURE request for an endpoint */
void handle_usb_request(u32 usb_num, u8 *setup_packet) {
    u8 request = setup_packet[1];
    u8 ep_addr = setup_packet[4];

    /* Check if the host is requesting to clear a stall condition */
    if (request == 0x01U) { /* USB_REQ_CLEAR_FEATURE */
        if (ca_usb_ep_clear_stall(usb_num, ep_addr)) {
            /* Successfully cleared stall, now send ZLP to acknowledge status */
            ca_usb_ep_write(usb_num, 0x80U, NULL, 0U);
        } else {
            /* Log error or handle failure to clear stall */
            /* ca_printf("Failed to clear stall on EP 0x%02X\n", ep_addr); */
        }
    }
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ep_clear_stall and why is it important in USB communication?
A: You should call ca_usb_ep_clear_stall when an endpoint is in a STALL state, typically after an error condition such as a USB transfer error or a protocol violation. This function is important because it allows the endpoint to recover from the STALL state and resume normal USB communication. It is usually invoked after detecting an error condition and before attempting to re-initiate a USB transfer.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_ep_clear_stall with caOS types?
A: bool result = ca_usb_ep_clear_stall(0, 0x81); if (result) { // Endpoint cleared successfully } else { // Handle error }

Parameters conf:0.90 **Q:** What are the valid ranges for usb_num and ep_addr parameters in ca_usb_ep_clear_stall, and what happens if they are out of range?
A: The usb_num parameter must be a valid USB controller number between 0 and the maximum number of available USB controllers. An invalid value may cause a crash or undefined behavior. The ep_addr parameter must be a valid endpoint address: 0x00-0x0F for IN endpoints and 0x80-0x8F for OUT endpoints. Using an invalid endpoint address may result in hardware errors or unexpected behavior.

Return conf:0.90 **Q:** What does the return value of ca_usb_ep_clear_stall indicate, and what causes it to return false?
A: The function returns true if the endpoint was successfully cleared from the STALL state. It returns false if the operation failed, which can be caused by an invalid endpoint address, an unavailable USB controller, or a hardware error. The function also may return false if the endpoint was not in a STALL state to begin with.

`ca_usb_ep_close`

Header: `caos/drivers/inc/usb.h:119`
Source: `caos/drivers/src/usb.c:97:101`
GUARD: `EN_USB`

```c
bool ca_usb_ep_close(u32 usb_num, u8 ep_addr)
```

Closes a specific USB endpoint to stop data transmission and release associated resources.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller (e.g., 0 for FS, 1 for HS). Must be less than USB_MAX_CTRL.
`ep_addr`	`u8`	The address of the endpoint to close (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2).

Ritorna:
Returns true if the endpoint was successfully closed, or false if the controller index is invalid or the operation failed.

Note:

- This function is not thread-safe and should not be called from an ISR. It is a blocking operation that interacts with the low-level USB driver to disable the hardware endpoint. A common mistake is calling this function while a transfer is still active or without checking if the USB controller is actually initialized, which can lead to undefined behavior or system instability. Always ensure the USB stack is in a state where closing the endpoint is safe, such as during a device disconnect or a configuration change.

Uso:

- This function is typically used during USB device state transitions, such as moving from an 'configured' state to an 'idle' or 'disconnected' state. It is often paired with ca_usb_ep_open to manage dynamic endpoint allocation. In a typical sequence, you would call ca_usb_ep_close when the host requests a configuration change or when the device is unplugged, ensuring that no further data is processed on that specific endpoint.

Esempio:

```c
/* Example: Closing USB endpoints during a device reset or disconnect event */
#define USB_NUM 0
#define EP_IN_ADDR 0x81
#define EP_OUT_ADDR 0x01

void handle_usb_disconnect(void) {
    /* Attempt to close the bulk endpoints to stop communication */
    bool closed_in = ca_usb_ep_close(USB_NUM, EP_IN_ADDR);
    bool closed_out = ca_usb_ep_close(USB_NUM, EP_OUT_ADDR);

    if (closed_in && closed_out) {
        ca_printf_n("[USB] Endpoints closed successfully.");
    } else {
        /* Log an error if the hardware failed to release the endpoints */
        ca_printf_n("[USB] Error: Failed to close one or more endpoints.");
    }
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ep_close and why is it important?
A: You should call ca_usb_ep_close when you want to close a specific USB endpoint that was previously opened with ca_usb_ep_open(). This function is important for resource management, especially after completing a USB transfer or when shutting down USB communication. It helps free up hardware resources and ensures proper cleanup of endpoint state.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_usb_ep_close in C with caOS types?

A: u32 usb_num = 0; u8 ep_addr = 0x81; bool result = ca_usb_ep_close(usb_num, ep_addr); if (!result) { // Handle error }

Parameters conf:0.90 **Q:** What do the parameters usb_num and ep_addr represent in ca_usb_ep_close, and what are valid values?

A: The parameter usb_num specifies the USB controller number (e.g., 0 for USB0), and must be a valid index between 0 and the maximum number of USB controllers available. The ep_addr specifies the endpoint address, where the MSB indicates direction (0 = OUT, 1 = IN). Valid endpoint addresses are typically 0x00 to 0x0F, with values outside this range potentially causing undefined behavior.

Return conf:0.95 **Q:** What does ca_usb_ep_close return, and what causes it to return false?

A: ca_usb_ep_close returns true if the endpoint was successfully closed. It returns false if the operation failed, which can happen if the endpoint was not previously opened, if the usb_num is invalid, or if a hardware error occurs during the closing process.

`ca_usb_ep_is_stalled`

Header: `caos/drivers/inc/usb.h:126`
Source: `caos/drivers/src/usb.c:109:113`
GUARD: `EN_USB`

```
bool ca_usb_ep_is_stalled(u32 usb_num, u8 ep_addr)
```

Checks if a specific USB endpoint is currently in a stalled state.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller. Must be less than USB_MAX_CTRL.
`ep_addr`	`u8`	The address of the endpoint to query (e.g., 0x81 for IN endpoint 1).

Ritorna:
Returns true if the endpoint is stalled, false otherwise. Returns false if the usb_num is invalid or the driver is not initialized.

Note:

- This function is non-blocking and performs a direct read of the endpoint status register. It is generally thread-safe depending on the underlying driver implementation, but it is not intended to be called from an ISR unless the driver explicitly supports it. The most common mistake is passing an invalid endpoint address or an uninitialized USB controller index, which will silently return false without indicating an error.

Uso:

- This function is primarily used during USB enumeration or control transfers when the host requests the status of an endpoint via the GET_STATUS request. It is typically paired with ca_usb_ep_write to send the status back to the host. Developers use this to verify if a previous error condition (stall) has been cleared or to report the current state of the communication pipe to the USB host.

Esempio:

```
/* Example: Handling a USB GET_STATUS request for an endpoint */
void handle_usb_get_status(u32 usb_num, u8 *setup, u16 wln) {
    u8 ep_addr = setup[4];
    /* Check if the requested endpoint is stalled */
```

```
    bool stalled = ca_usb_ep_is_stalled(usb_num, ep_addr);

    /* Prepare status response: bit 0 is stall status */
    u8 status[2] = { stalled ? 0x01U : 0x00U, 0x00U };

    /* Send the status back to the host using the control endpoint */
    ca_usb_ep_write(usb_num, 0x80U, status, (wln < 2U) ? wln : 2U);
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ep_is_stalled and why is it useful in USB communication?
A: You should call ca_usb_ep_is_stalled to check if a USB endpoint is currently in a stalled state, which indicates a communication error. This is useful for error handling and recovery in USB protocols, especially when implementing robust USB device drivers. It allows the application to detect and respond to endpoint stalls without blocking execution.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_ep_is_stalled with caOS types?
A: u32 usb_num = 0; u8 ep_addr = 0x81; bool is_stalled = ca_usb_ep_is_stalled(usb_num, ep_addr); if (is_stalled) { // Handle stall condition }

Parameters conf:0.90 **Q:** What are the valid ranges for usb_num and ep_addr parameters in ca_usb_ep_is_stalled?
A: The usb_num parameter must be a valid USB controller number between 0 and the maximum number of available USB controllers. The ep_addr parameter must be between 0x00-0x0F for IN endpoints or 0x80-0x8F for OUT endpoints. Passing invalid values may cause undefined behavior or errors.

Return conf:0.85 **Q:** What does the return value of ca_usb_ep_is_stalled indicate and what causes it to fail?
A: The function returns true if the endpoint is currently in a stalled state, and false if it is not. Failures can occur if the USB controller is not initialized, the endpoint is not configured correctly, or invalid parameters are passed such as an unconfigured endpoint or invalid USB number.

`ca_usb_ep_open`

Header: `caos/drivers/inc/usb.h:90`
Source: `caos/drivers/src/usb.c:43:47`
GUARD: `EN_USB`

```
bool ca_usb_ep_open(u32 usb_num, u8 ep_addr, ca_usb_ep_type_t type, u16
    mps)
```

Initializes and enables a specific USB endpoint for data transmission or reception.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB controller (e.g., 0 for FS, 1 for HS). Must be less than USB_MAX_CTRL.
ep_addr	u8	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Bit 7 is set for IN endpoints.
type	ca_usb_ep_type_t	The transfer type: CA_USB_EP_TYPE_BULK, CA_USB_EP_TYPE_INTR, or CA_USB_EP_TYPE_ISOC.
mps	u16	Maximum Packet Size in bytes. Must match the descriptor requirements for the chosen endpoint type.

Ritorna:
Returns true if the endpoint was successfully opened, false if the controller index is invalid or the hardware failed to configure the endpoint.

Note:

- This function is not thread-safe and must be called during the USB configuration phase, typically triggered by the host's SET_CONFIGURATION request. It is not intended to be called from an ISR. The USB controller must be fully initialized via the driver's init sequence before calling this. A common mistake is providing an incorrect MPS value that does not align with the USB specification for the specific endpoint type, which will cause the host to reject the device.

Uso:

- This function is used during the USB device enumeration process to prepare endpoints for data exchange. It is typically called inside a callback function (like an 'on_configure' handler) after the USB device has been assigned an address by the host. It is usually paired with ca_usb_ep_write or ca_usb_ep_read to perform actual data transfers once the endpoints are open.

Esempio:

```
/* Example: Opening endpoints for a custom USB device */
void custom_on_configure(const ca_usb_device_type_t *cfg) {
    u32 n = ca_usb_dev_mng_get_num();
    u16 mps = 64; // Standard Full-Speed Bulk MPS

    // Open Bulk IN endpoint (0x81)
    if (!ca_usb_ep_open(n, 0x81, CA_USB_EP_TYPE_BULK, mps)) {
        // Handle error: log failure or trigger system reset
        return;
    }

    // Open Bulk OUT endpoint (0x01)
    if (!ca_usb_ep_open(n, 0x01, CA_USB_EP_TYPE_BULK, mps)) {
        // Handle error: log failure
        return;
    }

    // Endpoints are now ready for ca_usb_ep_write or ca_usb_ep_read
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ep_open in a caOS application?

A: You should call ca_usb_ep_open after initializing the USB hardware with ca_usb_hw_init and configuring the GPIOs appropriately. It is used to open a specific USB endpoint for data transfer, typically before starting any USB communication such as sending or receiving data on that endpoint.

Code example conf:0.90 **Q:** Can you show a minimal C code example using ca_usb_ep_open with caOS types?
A: u32 usb_num = 0; u8 ep_addr = 0x81; ca_usb_ep_type_t type = CA_USB_EP_TYPE_BULK; u16 mps = 64; bool result = ca_usb_ep_open(usb_num, ep_addr, type, mps);

Parameters conf:0.90 **Q:** What are the valid values for the endpoint address and type parameters in ca_usb_ep_open?
A: The endpoint address (ep_addr) must be between 0x00-0x0F for IN endpoints or 0x80-0x8F for OUT endpoints. The type parameter must be one of CA_USB_EP_TYPE_CTRL, USB_EP_TYPE_ISO, CA_USB_EP_TYPE_BULK, or USB_EP_TYPE_INT. Using invalid values may cause hardware errors or unpredictable behavior.

Return conf:0.90 **Q:** What does it mean when ca_usb_ep_open returns false?
A: A return value of false indicates that the endpoint could not be opened successfully. This can happen due to invalid parameters, insufficient resources, or hardware errors. It is important to check the parameters passed to the function and ensure the USB hardware is properly initialized before calling this function.

`ca_usb_ep_read`

Header: `caos/drivers/inc/usb.h:96`
Source: `caos/drivers/src/usb.c:55:59`
GUARD: `EN_USB`

```
u16 ca_usb_ep_read(u32 usb_num, u8 ep_addr, u8 *buf, u16 max_len)
```

Reads data from a specific USB endpoint into a provided buffer.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller. Must be less than USB_MAX_CTRL.
`ep_addr`	`u8`	The endpoint address (e.g., 0x00 for EP0, 0x81 for IN, 0x01 for OUT).
`buf`	`u8 *`	Pointer to the memory buffer where received data will be stored.
`max_len`	`u16`	The maximum number of bytes to read. Must not exceed the buffer size.

Ritorna:
Returns the number of bytes actually read (u16). Returns 0 if the USB controller index is invalid, the controller is not initialized, or no data is available.

Note:

- This function is a wrapper that delegates to the specific hardware driver implementation. It is generally non-blocking in the sense that it returns immediately with the data currently available in the endpoint buffer. It is not inherently thread-safe if multiple tasks access the same endpoint simultaneously, so ensure proper synchronization or task-exclusive access. Do not call this from an ISR unless the underlying driver implementation explicitly supports it, as it may involve complex buffer management or synchronization primitives that are unsafe in interrupt context. A common mistake is providing a buffer smaller than the actual incoming packet size, which can lead to memory corruption or truncated data.

Uso:

- This function is typically used within the USB stack's data processing loop or inside a callback triggered by a USB event. It is used to retrieve control requests (like SET_LINE_CODING in CDC) or bulk data (like CBW in MSC). It is usually paired with ca_usb_ep_write to send responses or status packets back to the host. In a typical sequence, you wait for a USB event, call this function to pull the data into a local buffer, process the data, and then potentially send an acknowledgment or the requested data back.

Esempio:

```c
/* Example: Reading a setup packet from EP0 */
u32 n = ca_usb_dev_mng_get_num();
u8 rx_buffer[8];

/* Attempt to read up to 8 bytes from Endpoint 0 */
u16 bytes_received = ca_usb_ep_read(n, 0x00U, rx_buffer, sizeof(rx_buffer));

if (bytes_received >= 7U) {
    /* Process the received setup data */
    ca_printf("Received %d bytes from host\n", bytes_received);
} else {
    /* Handle error or empty buffer case */
    ca_printf("No data or incomplete packet received\n");
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_usb_ep_read in a caOS application?
A: You should call ca_usb_ep_read when you need to receive data from a USB endpoint in a blocking manner. It is typically used after configuring and activating a USB endpoint, and it will wait until data arrives or a hardware timeout occurs. This function is not suitable for use inside an ISR because it is blocking and may cause deadlocks.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_usb_ep_read with caOS types?
A: u8 buffer[64]; u16 bytes_read = ca_usb_ep_read(0, 0x81, buffer, 64); if (bytes_read != 0 && bytes_read != 0xFFFF) { // Process received data }

Parameters conf:0.90 **Q:** What are the valid ranges for the usb_num and ep_addr parameters in ca_usb_ep_read?
A: The usb_num parameter must be either 0 or 1, representing USB0 or USB1 interfaces respectively. The ep_addr parameter must be between 0x00 and 0x0F, indicating the endpoint address. Values outside these ranges are considered invalid and may lead to errors.

Return conf:0.95 **Q:** What does a return value of 0xFFFF from ca_usb_ep_read indicate?
A: A return value of 0xFFFF indicates a critical error, such as an invalid buffer pointer or an invalid endpoint address. This means the function could not proceed due to a fundamental issue with the input parameters.

`ca_usb_ep_stall`

Header: `caos/drivers/inc/usb.h:112`
Source: `caos/drivers/src/usb.c:91:95`
GUARD: `EN_USB`

```c
void ca_usb_ep_stall(u32 usb_num, u8 ep_addr)
```

Forces a USB endpoint into a STALL state to signal a protocol error or unsupported request to the host.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB controller (e.g., 0 for FS, 1 for HS). Must be less than USB_MAX_CTRL.
ep_addr	u8	The address of the endpoint to stall (e.g., 0x80 for IN endpoint 0, 0x01 for OUT endpoint 1).

Ritorna:
void. If the parameters are invalid, the function returns silently without performing any action.

Note:

- This function is non-blocking and typically executes immediately by setting the STALL bit in the endpoint control register. It is generally thread-safe depending on the underlying hardware driver implementation, but it is not intended to be called from an ISR unless the driver explicitly supports it. The most common beginner mistake is calling this on an endpoint that is not yet initialized or already closed, which may lead to undefined behavior in the USB stack. Always ensure the USB controller is initialized and the endpoint is active before attempting to stall it.

Uso:

- This function is used during USB enumeration or data transfer to handle protocol violations, such as receiving an invalid Command Block Wrapper (CBW) in Mass Storage Class or an unsupported request during SETUP phase. It is typically paired with ca_usb_ep_open during initialization and ca_usb_ep_clear_stall when the error condition is resolved. In a typical workflow, if a host sends a request that the device cannot fulfill, the device calls this function to inform the host that the endpoint is halted, effectively forcing the host to perform error recovery.

Esempio:

```c
/* Example: Handling an unsupported USB request */
void handle_usb_setup(u32 usb_num, u8 *setup_packet) {
    /* Check if the request type is supported */
    if (setup_packet[1] != 0x01) {
        /* Unsupported request: Stall the control endpoint (0x80) */
        ca_usb_ep_stall(usb_num, 0x80U);
    } else {
        /* Proceed with valid request handling */
        // ... logic to process request ...
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ep_stall() in a USB communication context?
A: You should call ca_usb_ep_stall() when you need to temporarily halt data transmission on a specific USB endpoint, typically to signal an error or to indicate that the endpoint is not ready to receive more data. It is a low-level function used for direct hardware control and must be used carefully in control contexts.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_ep_stall() with caOS types?
A: u32 usb_num = 0; u8 ep_addr = 0x80; ca_usb_ep_stall(usb_num, ep_addr);

Parameters conf:0.90 **Q:** What do the parameters usb_num and ep_addr represent in ca_usb_ep_stall(), and what are valid values for them?

A: The parameter usb_num specifies the USB interface number (e.g., 0 for USB0), and must be a valid interface number defined in the system. The parameter ep_addr specifies the USB endpoint address (e.g., 0x80 for an IN endpoint, 0x00 for a control endpoint). Invalid values for either parameter may cause crashes or undefined behavior.

---

ca_usb_ep_write

Header: caos/drivers/inc/usb.h:93
Source: caos/drivers/src/usb.c:49:53
GUARD: EN_USB

```
bool ca_usb_ep_write(u32 usb_num, u8 ep_addr, const u8 *buf, u16 len)
```

Transmits data from the device to the USB host via a specific endpoint.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB controller instance. Must be less than USB_MAX_CTRL.
ep_addr	u8	The endpoint address (e.g., 0x80 for IN endpoint 0). Must be an endpoint previously opened with ca_usb_ep_open.
buf	const u8 *	Pointer to the data buffer to send. Can be NULL if len is 0 (used for ZLP - Zero Length Packet).
len	u16	Number of bytes to transmit. Must not exceed the maximum packet size configured for the endpoint.

Ritorna:
Returns true if the write request was successfully queued, false if the controller is invalid, the endpoint is not open, or the hardware is busy.

Note:

- This function is non-blocking and typically queues the data for the USB hardware to transmit. It is not inherently thread-safe for concurrent access to the same endpoint, so ensure only one task or ISR manages a specific endpoint at a time. It is a mandatory precondition that the USB controller is initialized and the specific endpoint has been opened via ca_usb_ep_open. A common beginner mistake is passing a buffer that goes out of scope (e.g., a local stack variable) before the USB hardware has finished transmitting the data, which leads to memory corruption on the wire.

Uso:

- This function is used in the USB stack to respond to host requests or send asynchronous data. It is typically paired with ca_usb_ep_open during initialization to prepare the endpoint. In control transfers, it is frequently used to send status packets or data descriptors, often with a NULL buffer and 0 length to signal a Zero Length Packet (ZLP) to the host, indicating the end of a control transaction.

Esempio:

```
/* Example: Sending a status response to the USB host */
#define USB_CTRL_IDX 0
#define EP_IN_0 0x80U

```

```c
void send_usb_status(void) {
    /* Send a Zero Length Packet (ZLP) to acknowledge a control request */
    bool success = ca_usb_ep_write(USB_CTRL_IDX, EP_IN_0, NULL, 0U);

    if (!success) {
        /* Log error: failed to queue USB packet */
        ca_printf("USB write failed!\n");
    }
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_usb_ep_write() in a caOS application?
A: You should call ca_usb_ep_write() when you need to send data from your application to a USB host via a specific USB endpoint. It is typically used after opening an endpoint with ca_usb_ep_open() and is essential for USB communication in device mode.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_usb_ep_write() with caOS types?
A: u8 data[64] = {0x01, 0x02, 0x03}; bool success = ca_usb_ep_write(0, 0x81, data, 3);

Parameters conf:0.90 **Q:** What are the valid values for the usb_num and ep_addr parameters in ca_usb_ep_write()?
A: The usb_num parameter must be 0 or 1, corresponding to USB1 and USB2 controllers respectively. The ep_addr parameter must be an IN endpoint address between 0x80 and 0x8F, where bit 7 indicates the direction (1 for IN). Using invalid values may cause undefined behavior or errors.

Return conf:0.95 **Q:** What does ca_usb_ep_write() return, and what causes it to return false?
A: The function returns true if the data was successfully written to the USB endpoint. It returns false if the operation failed, which can happen due to an unopened endpoint, a NULL buffer, or if the endpoint is busy or unavailable.

`ca_usb_fs_dev_clock_init`

Header: `caos/drivers/inc/ca_glue_hw.h:31`
GUARD: `EN_CA_GLUE_HW`

```c
extern void ca_usb_fs_dev_clock_init(u32 usb_num)
```

Initializes the hardware clock and power supply requirements for the USB Full-Speed peripheral.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to initialize (e.g., 0 for USB1, 1 for USB2). Value depends on the specific STM32 series hardware capabilities.

Ritorna:
void

Note:

- This function is hardware-specific and performs low-level register manipulation to enable the HSI48 oscillator, configure clock selection (CCIPR), and power up the USB transceiver. It is not thread-safe and must be called during the system initialization phase before any USB communication functions are invoked. It is strictly forbidden to call this from an ISR,

as it contains blocking 'while' loops waiting for hardware ready flags (e.g., HSI48RDY). A common mistake is calling this function multiple times or after the USB stack has already started, which can cause clock instability or peripheral lockups.

Uso:

- This function is the mandatory first step in the USB initialization sequence. It is typically called during the board support package (BSP) setup or early system boot. It must be followed by GPIO configuration (e.g., ca_usb_fs_dev_gpio_init) and the USB stack initialization (e.g., ca_usb_fs_dev_init) to ensure the peripheral is ready for enumeration.

Esempio:

```
/* Initialize the USB clock before starting the USB stack */
ca_usb_fs_dev_clock_init(0U);

/* Configure the physical pins for USB communication */
ca_usb_fs_dev_gpio_init(0U);

/* Initialize the USB peripheral logic */
ca_usb_fs_dev_init(0U);

/* Wait for the USB connection to be established */
if (ca_usb_cdc_wait_connected(1000U)) {
    /* USB is ready for data transmission */
    ca_usb_cdc_write((u8 *)"Hello World", 11U);
} else {
    /* Handle timeout or connection failure */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** At what point in the system boot sequence should I call ca_usb_fs_dev_clock_init?
A: It must be called during the system initialization phase, typically within the board support package (BSP) setup or early boot. It is the mandatory first step in the USB initialization sequence, which must be followed by GPIO configuration (ca_usb_fs_dev_gpio_init) and USB stack initialization (ca_usb_fs_dev_init).

Code example conf:0.90 **Q:** Provide a minimal example of how to initialize the USB clock using caOS types.
A: void system_init(void) { u32 usb_index = 0; ca_usb_fs_dev_clock_init(usb_index); ca_usb_fs_dev_gpio_init(usb_index); ca_usb_fs_dev_init(usb_index); }

Parameters conf:1.00 **Q:** What does the u32 usb_num parameter represent?
A: It represents the index of the USB peripheral to initialize (e.g., 0 for USB1, 1 for USB2). The valid values depend on the specific STM32 series hardware capabilities.

Error/Edge case conf:1.00 **Q:** What are the common pitfalls when calling ca_usb_fs_dev_clock_init?
A: Common mistakes include calling the function multiple times or invoking it after the USB stack has already started, which can lead to clock instability or peripheral lockups. Additionally, it must not be called from an ISR due to blocking loops.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_clock_init thread-safe or ISR-safe?
A: The function is not thread-safe and is strictly forbidden from being called within an ISR. It contains blocking 'while' loops that wait for hardware ready flags, such as HSI48RDY, making it unsuitable for interrupt context.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_clock_init differ across STM32 families?
A: Implementations vary significantly: F1xx/F4xx/F7xx often rely on existing PLLQ configurations and simple AHB/APB clock enabling, while H5xx, H7xx, and U5xx require explicit HSI48 oscillator activation, CRS (Clock Recovery System) synchronization to

USB SOF, and specific power supply management (e.g., PWR->USBSCR for H5xx, PWR->CR3 for H7xx, or PWR->SVMCR for U5xx).

---

ca_usb_fs_dev_connect

Header: caos/drivers/inc/ca_glue_hw.h:40
GUARD: EN_CA_GLUE_HW

```
extern void ca_usb_fs_dev_connect(u32 usb_num)
```

Enables the USB device pull-up resistor to signal presence to the host.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral to connect. Must be a valid peripheral ID supported by the hardware.

Ritorna:
void

Note:

- This function is non-blocking and performs a direct register write to the USB controller to release the 'Soft Disconnect' (SDIS) bit or enable the D+ pull-up. It is not thread-safe in the sense that it should only be called once the USB stack is fully initialized and ready to handle enumeration requests from the host. Calling this too early will cause the host to attempt enumeration before the device is ready, leading to failed connections or 'Device Descriptor Request Failed' errors. It is generally not intended to be called from an ISR, as it is part of the high-level device management sequence.

Uso:

- This function is the final step in the USB device initialization sequence. It is typically called by the USB management layer (e.g., ca_usb_dev_mng_start) only after the hardware has been clocked, GPIOs configured, and all required endpoints have been opened via ca_usb_fs_dev_ep_open. By keeping the pull-up disabled until this point, you ensure the host does not see the device until the firmware is prepared to respond to standard USB requests.

Esempio:

```
/* Initialize USB peripheral and endpoints before connecting */
ca_usb_fs_dev_init(0);

/* Open control endpoint 0 for enumeration */
ca_usb_fs_dev_ep_open(0, 0x00, USB_EP_TYPE_CONTROL, 64);

/* Now that we are ready to handle host requests, signal presence */
ca_usb_fs_dev_connect(0);

/* The host will now detect the device and start enumeration */
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the correct time to call ca_usb_fs_dev_connect in the USB initialization sequence?
A: It should be the final step in the initialization sequence, called only after the hardware is clocked, GPIOs are configured, and all required endpoints have been opened via

ca_usb_fs_dev_ep_open. This ensures the host does not attempt enumeration before the device is fully prepared.

Code example conf:0.90 **Q:** Provide a minimal code snippet showing how to connect the USB device using caOS types.
A: u32 usb_id = 0; /* Assuming peripheral index 0 */ ca_usb_fs_dev_ep_open(usb_id, 0x81, CA_USB_EP_TYPE_BULK, 64); ca_usb_fs_dev_connect(usb_id);

Parameters conf:1.00 **Q:** What does the u32 usb_num parameter represent in ca_usb_fs_dev_connect?
A: It represents the index of the USB peripheral to connect. The value must correspond to a valid peripheral ID supported by the specific hardware implementation.

Error/Edge case conf:1.00 **Q:** What happens if I call ca_usb_fs_dev_connect before initializing endpoints?
A: Calling this function too early causes the host to attempt enumeration before the device is ready to handle requests, which typically leads to failed connections or 'Device Descriptor Request Failed' errors.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_connect thread-safe or ISR-safe?
A: The function is non-blocking and performs a direct register write. It is not thread-safe and is not intended to be called from an ISR, as it is part of the high-level device management sequence.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_connect differ across STM32 families?
A: Most families (f4xx, f7xx, h7xx, u5xx) implement this by clearing the SDIS (Soft Disconnect) bit in the DCTL register of the DWC2 controller. In contrast, the h5xx family uses the BCDR register to set the DPPU (D+ pull-up) bit.

`ca_usb_fs_dev_disconnect`

Header: `caos/drivers/inc/ca_glue_hw.h:41`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_usb_fs_dev_disconnect(u32 usb_num)
```

Disconnects the USB Full-Speed device from the host by pulling the D+ line low or setting the disconnect bit.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to disconnect. Must be a valid peripheral index supported by the hardware (e.g., 0 or 1).

Ritorna:
void

Note:

- This function is non-blocking and performs a direct register write to the USB peripheral's control register. It is generally thread-safe as it performs an atomic register modification, but it should not be called from an ISR unless the specific hardware implementation guarantees atomic access. The primary purpose is to simulate a physical cable unplug event to the host computer, forcing the host to re-enumerate the device. A common beginner mistake is calling this function while the USB stack is actively transmitting data, which can lead to undefined behavior or data loss in the USB buffers.

Uso:

- This function is typically used during device initialization sequences or when implementing a software-controlled USB reset. It is often paired with ca_usb_fs_dev_connect to toggle the connection state, allowing the device to 're-plug' itself to the host without physical intervention. In a typical lifecycle, you might call this during a system reset or when the application detects a critical USB error that requires a full re-enumeration.

Esempio:

```c
/* Example: Force a USB re-enumeration by disconnecting and reconnecting */
void reset_usb_connection(u32 usb_id) {
    /* Disconnect the device from the host */
    ca_usb_fs_dev_disconnect(usb_id);

    /* Wait for a short period to ensure the host registers the disconnect */
    ca_os_delay_ms(500);

    /* Re-connect the device to trigger re-enumeration */
    ca_usb_fs_dev_connect(usb_id);
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use the ca_usb_fs_dev_disconnect function in my caOS application?
A: You should use this function during device initialization sequences, when implementing a software-controlled USB reset, or when the application detects a critical USB error that requires a full re-enumeration. It simulates a physical cable unplug event to force the host to re-enumerate the device.

Code example conf:0.90 **Q:** How do I implement a software-controlled USB reset using caOS functions?
A: You can toggle the connection state by calling the disconnect and connect functions. Example: void reset_usb(u32 usb_idx) { ca_usb_fs_dev_disconnect(usb_idx); /* Add delay here if needed */ ca_usb_fs_dev_connect(usb_idx); }

Parameters conf:1.00 **Q:** What does the u32 usb_num parameter represent and what are the valid values?
A: The usb_num parameter is the index of the USB peripheral to disconnect. It must be a valid peripheral index supported by the hardware, such as 0 or 1.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_disconnect differ across STM32 families?
A: Implementations vary by register and bit usage: F4, F7, H7, and U5 families use the DCTL register and the USB_OTG_DCTL_SDIS bit. The H5 family uses the BCDR register and the USB_BCDR_DPPU bit. The F1 family implementation is currently a stub that performs no action.

`ca_usb_fs_dev_ep_clear_stall`

Header: `caos/drivers/inc/ca_glue_hw.h:44`
GUARD: `EN_CA_GLUE_HW`

```c
extern bool ca_usb_fs_dev_ep_clear_stall(u32 usb_num, u8 ep_addr)
```

Clears the STALL condition on a specific USB endpoint to resume normal communication.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (e.g., 0 for FS, 1 for HS). Must be a valid peripheral index for the target MCU.
ep_addr	u8	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Must be a valid endpoint index.

Ritorna:
Returns true if the stall was successfully cleared, false if the endpoint address is invalid or the operation is not supported on the current hardware.

Note:

- This function is non-blocking and performs direct register manipulation on the USB OTG peripheral. It is generally not thread-safe if called concurrently from multiple tasks for the same endpoint, so ensure synchronization if necessary. It is typically safe to call from an ISR, but check specific hardware implementation constraints. A common beginner mistake is calling this function on an endpoint that has not been opened or initialized, which may lead to undefined behavior or system instability. Always ensure the endpoint is in a stalled state before attempting to clear it, as clearing a non-stalled endpoint may disrupt active data transfers.

Uso:

- This function is used during USB enumeration or error recovery when the host or device needs to reset the data toggle and clear the stall bit after a protocol error. It is typically paired with ca_usb_fs_dev_ep_stall to manage endpoint flow control. In a standard sequence, you would detect a stall condition, perform necessary cleanup or buffer resets, call this function to clear the hardware stall, and then resume data transmission or reception.

Esempio:

```
/* Example: Clearing a stall on IN endpoint 1 after a protocol error */
u8 ep_addr = 0x81; // Endpoint 1 IN
u32 usb_idx = 0;

// Check if the endpoint is actually stalled before clearing
if (ca_usb_fs_dev_ep_is_stalled(usb_idx, ep_addr)) {
    // Clear the stall condition to allow the host to resume communication
    if (ca_usb_fs_dev_ep_clear_stall(usb_idx, ep_addr)) {
        // Successfully cleared, proceed to re-enable data flow
    } else {
        // Handle error: failed to clear stall
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_fs_dev_ep_clear_stall in my USB stack?
A: You should call this function during USB enumeration or error recovery when the host or device needs to reset the data toggle and clear the stall bit after a protocol error. It is typically used to resume communication after a stall condition has been detected and handled.

Code example conf:1.00 **Q:** Provide a minimal example of how to clear a stall on endpoint 1 (IN).
A: u32 usb_idx = 0; u8 ep_addr = 0x81; if (ca_usb_fs_dev_ep_clear_stall(usb_idx, ep_addr)) { /* Stall cleared successfully */ }

Parameters conf:1.00 **Q:** What do the usb_num and ep_addr parameters represent?

A: usb_num is the index of the USB peripheral (e.g., 0 for FS, 1 for HS). ep_addr is the endpoint address, such as 0x81 for IN endpoint 1 or 0x02 for OUT endpoint 2. Both must be valid for the target MCU.

Return conf:1.00 **Q:** What does the boolean return value indicate?

A: It returns true if the stall was successfully cleared. It returns false if the endpoint address is invalid or if the operation is not supported on the current hardware.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using this function?

A: A common beginner mistake is calling this function on an endpoint that has not been opened or initialized, which may lead to undefined behavior or system instability. Additionally, clearing a non-stalled endpoint may disrupt active data transfers.

Behavior conf:1.00 **Q:** Is this function thread-safe or blocking?

A: The function is non-blocking and performs direct register manipulation. It is generally not thread-safe if called concurrently from multiple tasks for the same endpoint, so synchronization is required. It is typically safe to call from an ISR, but you should check specific hardware implementation constraints.

HW differences conf:1.00 **Q:** Are there differences in how this function is implemented across MCU families?

A: Yes. On F1xx and F7xx, the function is currently a stub that returns false. On F4xx, H7xx, and U5xx, it manipulates DWC2 registers like DIEPCTL and DOEPCTL. On H5xx, it interacts with R_CHEP registers and manages DTOG bits directly.

`ca_usb_fs_dev_ep_close`

Header: `caos/drivers/inc/ca_glue_hw.h:43`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_usb_fs_dev_ep_close(u32 usb_num, u8 ep_addr)
```

Safely disables and resets a specific USB device endpoint hardware configuration.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for FS, 1 for HS). Must be a valid peripheral index.
`ep_addr`	`u8`	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). EP0 is not allowed.

Ritorna:
Returns true if the endpoint was successfully closed, false if the endpoint was already closed, invalid (EP0), or if the peripheral index is out of range.

Note:

- This function is blocking because it waits for hardware handshake signals (NAK/EPDISD) to ensure the endpoint is safely disabled before clearing registers. It is not thread-safe and must not be called from an ISR, as it performs busy-waiting loops that could hang the system if the hardware is unresponsive. A common mistake is attempting to close EP0, which is reserved for control transfers and managed by the stack; the function will return false immediately. Ensure the endpoint is no longer being accessed by the USB stack before calling this, as it clears internal state buffers and hardware masks.

Uso:

- This function is typically used during USB device re-enumeration or when a specific interface is being disabled to free up resources. It is the final step in the teardown sequence: first, stop data transmission/reception, then call this function to reset the hardware state, and finally update the application-level endpoint status. It is often paired with ca_usb_fs_dev_ep_open to re-initialize the endpoint with new parameters after a configuration change.

Esempio:

```c
/* Example: Safely closing an IN endpoint before re-configuration */
u8 ep_addr = 0x81; // IN endpoint 1
u32 usb_idx = 0;

if (ca_usb_fs_dev_ep_close(usb_idx, ep_addr)) {
    /* Endpoint hardware is now disabled and buffers are flushed */
    ca_printf("Endpoint 0x%02X closed successfully.\n", ep_addr);
} else {
    /* Endpoint was already closed or invalid */
    ca_printf("Failed to close endpoint 0x%02X.\n", ep_addr);
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_fs_dev_ep_close in my USB application?
A: This function is used during USB device re-enumeration or when disabling a specific interface to free resources. It should be the final step in a teardown sequence: first stop data transmission/reception, then call this function to reset hardware, and finally update application-level status.

Code example conf:1.00 **Q:** Provide a minimal example of how to close an IN endpoint using caOS types.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; if (ca_usb_fs_dev_ep_close(usb_idx, ep_addr)) { /* Endpoint closed successfully */ }

Parameters conf:1.00 **Q:** What are the constraints on the ep_addr parameter?
A: The ep_addr must be a valid endpoint address (e.g., 0x81 for IN, 0x02 for OUT). EP0 is strictly reserved for control transfers and is not allowed; attempting to close it will cause the function to return false.

Return conf:1.00 **Q:** What does a return value of false indicate?
A: A false return indicates that the endpoint was already closed, the provided endpoint address was EP0, the peripheral index was out of range, or the operation failed to complete.

Error/Edge case conf:1.00 **Q:** What are the common mistakes when using ca_usb_fs_dev_ep_close?
A: A common mistake is attempting to close EP0, which is managed by the stack. Additionally, failing to stop data transmission/reception before calling this function can lead to issues, as the function clears internal state buffers and hardware masks.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_ep_close safe to call from an interrupt service routine (ISR)?
A: No, it is not ISR-safe. The function is blocking and uses busy-waiting loops to wait for hardware handshake signals (NAK/EPDISD). Calling it from an ISR could hang the system if the hardware is unresponsive.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_close differ across STM32 families?
A: Implementations vary significantly: F1xx and F7xx provide stubs that return false, while F4xx, H7xx, and U5xx perform complex register-level operations (e.g., DWC2_GLB, DWC2_DEV, DIEPCTL, DOEPCTL) to disable endpoints and flush FIFOs. H5xx uses a simplified abstraction with ep_set_stat_tx/rx functions.

ca_usb_fs_dev_ep_is_stalled

Header: caos/drivers/inc/ca_glue_hw.h:45
GUARD: EN_CA_GLUE_HW

```
extern bool ca_usb_fs_dev_ep_is_stalled(u32 usb_num, u8 ep_addr)
```

Checks if a specific USB endpoint is currently in a stalled state.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (e.g., 0 for USB_FS). Must be within the hardware-supported range.
ep_addr	u8	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Must be a valid endpoint index.

Ritorna:
Returns true if the endpoint is stalled, false otherwise. Returns false if the endpoint address is invalid or the peripheral is not initialized.

Note:

- This function is non-blocking and performs a direct register read from the USB hardware controller. It is thread-safe in the sense that it performs a read-only operation, but it does not provide synchronization against concurrent modifications of the endpoint state. It is safe to call from an ISR, as it does not involve OS primitives or blocking calls. A common mistake is passing an invalid endpoint address or failing to check if the USB peripheral is actually initialized before querying its status.

Uso:

- This function is typically used during USB error handling or protocol recovery sequences. It is often paired with ca_usb_fs_dev_ep_clear_stall when a host requests a clear feature on a stalled endpoint. Developers use it to verify the current state of the hardware before attempting to send or receive data, ensuring that the endpoint is not in a 'halted' state that would cause data transfers to fail.

Esempio:

```
/* Check if endpoint 1 (IN) is stalled before attempting to send data */
#define EP_IN_1 0x81

void check_and_recover_ep(u32 usb_idx) {
    if (ca_usb_fs_dev_ep_is_stalled(usb_idx, EP_IN_1)) {
        /* Endpoint is stalled, clear the stall condition to resume communication */
        /* Note: ca_usb_fs_dev_ep_clear_stall is the function to reset the stall bit */
        ca_usb_fs_dev_ep_clear_stall(usb_idx, EP_IN_1);
    } else {
        /* Endpoint is healthy, proceed with data transmission */
        // ca_usb_fs_dev_ep_write(usb_idx, EP_IN_1, buffer, size);
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_usb_fs_dev_ep_is_stalled in my USB stack?

A: It is typically used during USB error handling or protocol recovery sequences. It is often paired with ca_usb_fs_dev_ep_clear_stall when a host requests a clear feature on a stalled endpoint to verify the hardware state before attempting further data transfers.

Code example conf:1.00 **Q:** Provide a minimal example of checking if endpoint 1 IN is stalled.

A: u32 usb_idx = 0; u8 ep_addr = 0x81; if (ca_usb_fs_dev_ep_is_stalled(usb_idx, ep_addr)) { /* Handle stalled endpoint */ }

Parameters conf:1.00 **Q:** What are the requirements for the ep_addr parameter?

A: The ep_addr must be a valid endpoint index (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Passing an invalid endpoint address will cause the function to return false.

Return conf:1.00 **Q:** What does a return value of false indicate?

A: A return value of false indicates that the endpoint is not stalled, the endpoint address provided is invalid, or the USB peripheral is not initialized.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_is_stalled differ across MCU families?

A: Implementations vary significantly: F4xx, H7xx, and U5xx use DWC2 registers (DIEPCTL/DOEPCTL), while H5xx uses R_CHEP registers (USB_CHEP_TX_STTX/USB_CHEP_ Notably, F1xx and F7xx implementations are currently stubs that return false.

`ca_usb_fs_dev_ep_open`

Header: `caos/drivers/inc/ca_glue_hw.h:34`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_usb_fs_dev_ep_open(u32 usb_num, u8 ep_addr,
    ca_usb_ep_type_t type, u16 mps)
```

Initializes and enables a specific USB endpoint for data transmission or reception.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for FS, 1 for HS). Must be within valid hardware range.
`ep_addr`	`u8`	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Bit 7 indicates direction.
`type`	`ca_usb_ep_type_t`	The transfer type (Control, Bulk, Interrupt, or Isochronous). Must match the descriptor.
`mps`	`u16`	Maximum Packet Size in bytes. Must not exceed the hardware buffer capacity.

Ritorna:
Returns true if the endpoint was successfully configured and enabled, false if the endpoint index is invalid or the hardware failed to initialize.

Note:

- This function is not thread-safe and must be called during the USB enumeration process or when reconfiguring an interface. It is typically not callable from an ISR as it performs direct hardware register manipulation. A common beginner mistake is providing an incorrect MPS value that exceeds the physical buffer size, which can lead to memory corruption or silent data loss. Ensure the USB peripheral clock and GPIOs are initialized via ca_usb_fs_dev_clock_init and ca_usb_fs_dev_gpio_init before calling this.

Uso:

- This function is used during the USB device setup phase, specifically after receiving a SET_CONFIGURATION or SET_INTERFACE request from the host. It is part of a sequence: first, initialize the USB core with ca_usb_fs_dev_init, then open the required endpoints using this function, and finally enable the device connection via ca_usb_fs_dev_connect. It is paired with ca_usb_fs_dev_ep_close when the interface is disabled or the device is disconnected.

Esempio:

```c
/* Example: Opening Bulk IN and OUT endpoints for a custom USB interface */
#define EP_BULK_IN  0x81
#define EP_BULK_OUT 0x01

void setup_usb_endpoints(u32 usb_idx) {
    /* Configure Bulk IN endpoint with 64 bytes MPS */
    if (!ca_usb_fs_dev_ep_open(usb_idx, EP_BULK_IN, CA_USB_EP_TYPE_BULK, 64)) {
        /* Handle error: log or trigger system reset */
    }

    /* Configure Bulk OUT endpoint with 64 bytes MPS */
    if (!ca_usb_fs_dev_ep_open(usb_idx, EP_BULK_OUT, CA_USB_EP_TYPE_BULK, 64)) {
        /* Handle error: log or trigger system reset */
    }

    /* Now the endpoints are ready to receive/send data via
    ca_usb_fs_dev_ep_read/write */
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** At what point in the USB device lifecycle should I call ca_usb_fs_dev_ep_open?
A: This function should be called during the USB device setup phase, specifically after the host sends a SET_CONFIGURATION or SET_INTERFACE request. It must be executed after initializing the USB core with ca_usb_fs_dev_init and before enabling the connection via ca_usb_fs_dev_connect.

Code example conf:0.90 **Q:** Provide a minimal example of how to open an IN endpoint using caOS types.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; ca_usb_ep_type_t type = CA_USB_EP_BULK; u16 mps = 64; bool success = ca_usb_fs_dev_ep_open(usb_idx, ep_addr, type, mps);

Parameters conf:1.00 **Q:** How do I correctly specify the ep_addr parameter?
A: The ep_addr is a u8 where the lower bits represent the endpoint number and bit 7 indicates the direction. For example, 0x81 represents IN endpoint 1, while 0x02 represents OUT endpoint 2.

Return conf:1.00 **Q:** What does a false return value from ca_usb_fs_dev_ep_open indicate?
A: A return value of false indicates that the endpoint index is invalid (e.g., exceeds the hardware limit) or that the hardware failed to initialize the endpoint configuration.

Error/Edge case conf:1.00 **Q:** What is a common mistake when configuring the Maximum Packet Size (MPS)?
A: A common beginner mistake is providing an MPS value that exceeds the physical buffer capacity of the hardware. This can lead to memory corruption or silent data loss.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_ep_open safe to call from an Interrupt Service Routine (ISR)?
A: No, this function is not thread-safe and is typically not callable from an ISR because it performs direct hardware register manipulation. It must be called during the USB enumeration process or interface reconfiguration.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_open differ between the H5xx family and the F4xx/F7xx families?

A: The H5xx implementation uses a packet memory area (PMA) approach with registers like R_CHEP and R_BTABLE, whereas the F4xx, F7xx, and H7xx families utilize the DWC2 OTG controller, manipulating registers like DIEPCTL and DOEPCTL.

---

ca_usb_fs_dev_ep_read

Header: caos/drivers/inc/ca_glue_hw.h:36
GUARD: EN_CA_GLUE_HW

```
extern u16 ca_usb_fs_dev_ep_read(u32 usb_num, u8 ep_addr, u8 *buf, u16
    max_len)
```

Reads data from a specific USB device endpoint into a provided buffer.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (usually 0). Must be within valid hardware range.
ep_addr	u8	The endpoint address (e.g., 0x01 for EP1 OUT). Must be an OUT endpoint; IN endpoints will return 0.
buf	u8 *	Pointer to the destination buffer. Must not be NULL.
max_len	u16	Maximum number of bytes to copy. If the received packet is larger, only this amount is copied.

Ritorna:
Returns the number of bytes actually copied into the buffer. Returns 0 if the endpoint is empty, invalid, or if an error occurs (e.g., NULL buffer or IN endpoint).

Note:

- This function is non-blocking and retrieves data already present in the internal USB receive queues. It is generally thread-safe regarding the queue management, but it interacts with hardware registers that may be modified by the USB ISR; therefore, it uses critical sections internally to prevent race conditions during endpoint re-arming. A common beginner mistake is calling this function in a tight loop without checking if data is actually available, which wastes CPU cycles; instead, wait for a signal or event indicating that data has arrived. Ensure the endpoint has been successfully opened with ca_usb_fs_dev_ep_open before attempting to read.

Uso:

- This function is typically used in a dedicated USB task or a callback triggered by a data-ready event. The standard sequence is: 1) Initialize the USB peripheral, 2) Open the desired endpoint using ca_usb_fs_dev_ep_open, 3) Wait for a notification (e.g., via ca_event_wait) that data is ready, 4) Call ca_usb_fs_dev_ep_read to copy the data into a local buffer, and 5) Process the data. It is often paired with ca_usb_fs_dev_ep_write to implement bidirectional communication.

Esempio:

```
/* Assuming USB is initialized and EP1 OUT is open */
u8 rx_buffer[64];
u16 bytes_received;

```

```c
/* Wait for an event indicating data arrival */
ca_event_wait(usb_data_event, 1000);

/* Attempt to read up to 64 bytes from EP1 OUT */
bytes_received = ca_usb_fs_dev_ep_read(0, 0x01, rx_buffer, 64);

if (bytes_received > 0) {
    /* Process the received data */
    ca_printf("Received %d bytes\n", bytes_received);
} else {
    /* Handle empty queue or error */
    ca_printf("No data available or read error\n");
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_usb_fs_dev_ep_read in a caOS application?
A: It should be called after initializing the USB peripheral and opening the endpoint with ca_usb_fs_dev_ep_open. You should wait for a notification, such as via ca_event_wait, indicating that data is ready, rather than polling in a tight loop.

Code example conf:1.00 **Q:** Provide a minimal example of reading data from USB endpoint 1 using caOS types.
A: u8 buffer[64]; u16 received = ca_usb_fs_dev_ep_read(0, 0x01, buffer, 64); if (received > 0) { /* process data */ }

Parameters conf:1.00 **Q:** What are the constraints on the ep_addr parameter for ca_usb_fs_dev_ep_read?
A: The ep_addr must represent an OUT endpoint. If an IN endpoint address is provided, the function will return 0. The endpoint must also be within the valid hardware range defined for the specific MCU.

Return conf:1.00 **Q:** What does a return value of 0 from ca_usb_fs_dev_ep_read signify?
A: A return value of 0 indicates that the endpoint is empty, the endpoint address is invalid (e.g., an IN endpoint), the buffer pointer is NULL, or an error occurred during the read operation.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_usb_fs_dev_ep_read?
A: A common beginner mistake is calling the function in a tight loop without checking if data is actually available, which wastes CPU cycles. It is better to wait for a signal or event indicating data arrival.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_ep_read thread-safe and blocking?
A: The function is non-blocking and retrieves data already present in internal queues. It is generally thread-safe regarding queue management and uses internal critical sections to prevent race conditions with the USB ISR during endpoint re-arming.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_read differ between the F7xx and H5xx families?
A: The F7xx implementation uses DMA (dma_rx) and directly manipulates DOEPDMA and DOEPTSIZ registers to re-arm the endpoint. The H5xx implementation manages RX rings and uses R_CHEP registers to check status and set RX_VALID/NAK states, specifically avoiding RXBD rewrites to prevent ghost length-0 packets.

`ca_usb_fs_dev_ep_stall`

Header: `caos/drivers/inc/ca_glue_hw.h:42`
GUARD: `EN_CA_GLUE_HW`

```c
extern void ca_usb_fs_dev_ep_stall(u32 usb_num, u8 ep_addr)
```

Forces a USB endpoint into the STALL state to signal a protocol error or lack of resources to the host.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 or 1). On single-controller chips, this is often ignored.
`ep_addr`	`u8`	The endpoint address. Bit 7 is the direction (1 for IN, 0 for OUT). Bits 0-3 define the endpoint number.

Ritorna:
void

Note:

- This function is non-blocking and executes immediately by modifying hardware registers. It is generally safe to call from an ISR, as it performs simple register writes without waiting for external events. The most common mistake is passing an invalid endpoint address or forgetting that stalling an endpoint stops all communication on that pipe until the host sends a CLEAR_FEATURE request. Ensure the USB peripheral is properly initialized before calling this, otherwise, the register access may cause a hard fault.

Uso:

- Use this function when your USB stack detects an invalid request or a buffer overflow condition that requires the host to stop sending data. It is typically paired with ca_usb_fs_dev_ep_clear_stall, which is used once the error condition is resolved and the host requests to resume communication. In a standard USB device implementation, you would call this inside your control transfer handler when a setup packet contains unsupported parameters.

Esempio:

```
/* Example: Stalling an endpoint due to an invalid data request */
void handle_usb_request(u8 ep_addr, u32 length) {
    if (length > MAX_BUFFER_SIZE) {
        /* Signal the host that this endpoint cannot process the request */
        ca_usb_fs_dev_ep_stall(0, ep_addr);
    } else {
        /* Proceed with normal data processing */
        // ca_usb_fs_dev_ep_read(0, ep_addr, buffer, length);
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use the ca_usb_fs_dev_ep_stall function in my USB device implementation?
A: You should call this function when your USB stack detects an invalid request or a buffer overflow condition that requires the host to stop sending data. It is typically used in the control transfer handler when a setup packet contains unsupported parameters.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to stall endpoint 1 IN using caOS types.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; ca_usb_fs_dev_ep_stall(usb_idx, ep_addr);

Parameters conf:1.00 **Q:** How do I correctly format the ep_addr parameter for ca_usb_fs_dev_ep_stall?
A: The ep_addr parameter is a u8 where bits 0-3 define the endpoint number and bit 7 indicates the direction (1 for IN, 0 for OUT).

Error/Edge case conf:1.00 **Q:** What are the common pitfalls when calling ca_usb_fs_dev_ep_stall?

A: Common mistakes include passing an invalid endpoint address, failing to initialize the USB peripheral before calling (which may cause a hard fault), or forgetting that stalling stops all communication on that pipe until the host sends a CLEAR_FEATURE request.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_stall differ across STM32 families?

A: Implementations vary significantly: F1xx provides a dummy implementation, F4xx/F7xx/U5xx directly manipulate DWC2_EPIN/EPOUT registers and call ep0_out_arm for endpoint 0, H7xx includes bounds checking for usb_num, and H5xx uses abstraction functions ep_set_stat_tx/rx with internal bounds checking against USB_EP_MAX.

---

ca_usb_fs_dev_ep_write

Header: `caos/drivers/inc/ca_glue_hw.h:35`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_usb_fs_dev_ep_write(u32 usb_num, u8 ep_addr, const u8 *
    buf, u16 len)
```

Writes data to a specific USB device endpoint by queuing it for transmission.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (usually 0).
`ep_addr`	`u8`	The endpoint address (e.g., 0x81 for IN endpoint 1). Must be an IN endpoint.
`buf`	`const u8 *`	Pointer to the data buffer to be sent. Can be NULL if len is 0.
`len`	`u16`	Number of bytes to write. Must not exceed the endpoint's buffer capacity.

Ritorna:
Returns true if the data was successfully queued for transmission, false otherwise (e.g., invalid endpoint, buffer full, or hardware busy).

Note:

- This function is thread-safe and uses internal critical sections to protect the transmission ring buffer from concurrent access by multiple tasks or ISRs. It is non-blocking; if the internal queue is full, it returns false immediately, allowing the caller to decide whether to retry or yield. A common mistake is assuming the data is sent immediately; the function only copies data into the driver's internal queue. Ensure the endpoint has been properly opened with ca_usb_fs_dev_ep_open before calling this function. Misuse, such as passing an OUT endpoint address, will result in an immediate false return.

Uso:

- Used in USB device applications to send data to the host. It is typically called after the USB connection is established and the endpoint is configured. In a standard workflow, the application initializes the USB stack, opens the required endpoints, and then calls this function whenever data is ready to be transmitted. If the function returns false due to a full queue, the application should use ca_os_yield or a small delay before attempting to resend the data.

Esempio:

```
/* Example: Sending a status message over a USB IN endpoint */
#define EP_IN_ADDR 0x81
```

```

void send_usb_status(const u8 *data, u16 length) {
    /* Attempt to write data to the USB endpoint */
    if (!ca_usb_fs_dev_ep_write(0, EP_IN_ADDR, data, length)) {
        /* If queue is full, wait briefly and try again */
        ca_os_delay_ms(10);
        /* Note: In a real application, implement a retry counter or buffer management */
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_fs_dev_ep_write in my application?
A: You should call this function after the USB connection is established and the target endpoint has been successfully initialized using ca_usb_fs_dev_ep_open. It is used to queue data for transmission to the host whenever your application has data ready to send.

Code example conf:1.00 **Q:** Provide a minimal example of how to send data using ca_usb_fs_dev_ep_write.
A: u8 data[] = {0x01, 0x02, 0x03}; u32 usb_idx = 0; u8 ep = 0x81; if (!ca_usb_fs_dev_ep_write(usb_idx, ep, data, 3)) { ca_os_yield(); }

Parameters conf:1.00 **Q:** What are the constraints on the ep_addr and len parameters?
A: The ep_addr must represent an IN endpoint (e.g., 0x81). Passing an OUT endpoint address will result in an immediate false return. The len parameter must not exceed the endpoint's configured buffer capacity.

Return conf:1.00 **Q:** What does a false return value from ca_usb_fs_dev_ep_write indicate?
A: A false return indicates the data was not queued. This can happen if the endpoint address is invalid, the internal transmission queue is full, the hardware is busy, or the endpoint was not properly opened.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_usb_fs_dev_ep_write?
A: A common mistake is assuming the data is sent immediately. The function only copies data into the driver's internal queue. If the queue is full, the function returns false, and the application should handle this by yielding or retrying later.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_ep_write safe to call from multiple tasks or ISRs?
A: Yes, the function is thread-safe. It uses internal critical sections to protect the transmission ring buffer from concurrent access by multiple tasks or ISRs, preventing data corruption.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_ep_write differ between F4xx and H5xx families?
A: On F4xx, the driver uses a ring buffer and checks for free slots in the queue. On H5xx, the driver manages PMA (Packet Memory Area) and must explicitly handle ZLP (Zero Length Packet) logic for multi-packet transfers that are exact multiples of the MPS, as PMA does not packetize in hardware.

`ca_usb_fs_dev_get_speed`

Header: `caos/drivers/inc/ca_glue_hw.h:38`
GUARD: `EN_CA_GLUE_HW`

```
extern ca_usb_speed_t ca_usb_fs_dev_get_speed(u32 usb_num)
```

Retrieves the current operational speed of the specified USB Full-Speed device.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to query. Valid values depend on the hardware configuration (usually 0 or 1 for multi-USB systems).

Ritorna:
Returns a ca_usb_speed_t enum value (e.g., CA_USB_SPEED_FS). If the hardware does not support speed detection or the index is invalid, it typically defaults to CA_USB_SPEED_FS.

Note:

- This function is non-blocking and thread-safe as it typically reads from a cached state variable maintained by the USB driver. It is safe to call from an ISR because it performs a simple memory read without acquiring mutexes or waiting for hardware events. The most common mistake is assuming the speed can change dynamically without the USB stack re-enumerating; always ensure the USB peripheral has been initialized via the appropriate driver init function before calling this.

Uso:

- This function is used during the USB enumeration process or when debugging connection issues to verify if the device has negotiated the expected speed. It is typically called after the USB stack has been initialized and the device is connected to a host. Developers often pair this with ca_usb_cdc_wait_connected to ensure the link is active before checking the speed, or use it in diagnostic logs to confirm hardware capabilities.

Esempio:

```c
/* Check the speed of the first USB peripheral */
ca_usb_speed_t speed = ca_usb_fs_dev_get_speed(0);

/* Log the detected speed for debugging purposes */
if (speed == CA_USB_SPEED_FS) {
    /* USB is operating at Full Speed (12 Mbps) */
    ca_printf("USB device 0 is running at Full Speed\n");
} else {
    /* Handle unexpected speed or error states */
    ca_printf("USB device 0 speed status: %d\n", (int)speed);
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_usb_fs_dev_get_speed in my application?
A: You should call this function after the USB stack has been initialized and the device is connected to a host. It is typically used during the USB enumeration process or for diagnostic logging to verify the negotiated speed. It is recommended to pair this with ca_usb_cdc_wait_connected to ensure the link is active before checking.

Code example conf:1.00 **Q:** Provide a minimal example of how to check the USB speed in caOS.
A: u32 usb_idx = 0; ca_usb_speed_t speed = ca_usb_fs_dev_get_speed(usb_idx); if (speed == CA_USB_SPEED_FS) { /* Handle Full-Speed logic */ }

Parameters conf:0.90 **Q:** What does the usb_num parameter represent and what are its valid values?
A: The usb_num parameter is the index of the USB peripheral to query. Valid values depend on the hardware configuration, typically 0 or 1 for multi-USB systems. Note that some implementations ignore this parameter if the hardware only supports a single USB instance.

Return conf:0.95 **Q:** What does the return value of ca_usb_fs_dev_get_speed indicate, and what happens if it fails?

A: It returns a ca_usb_speed_t enum value, such as CA_USB_SPEED_FS. If the hardware does not support speed detection or if an invalid index is provided, the function typically defaults to returning CA_USB_SPEED_FS.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_get_speed vary across different STM32 families?

A: Implementations vary: F1xx and H5xx return a hardcoded CA_USB_SPEED_FS. F4xx, F7xx, and U5xx return a cached speed value from a global state (g_st.speed) and ignore the usb_num parameter. H7xx is unique in that it checks the index against a global array (g_usb[usb_num].speed) to support multiple peripherals.

---

ca_usb_fs_dev_gpio_init

Header: `caos/drivers/inc/ca_glue_hw.h:32`
GUARD: `EN_CA_GLUE_HW`

```
extern void ca_usb_fs_dev_gpio_init(u32 usb_num)
```

Configures the physical GPIO pins required for USB Full-Speed peripheral operation.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral to initialize (e.g., 0 for USB_OTG_FS1). Values depend on the specific MCU architecture.

Ritorna:
void

Note:

- This function is non-blocking and performs direct register manipulation to set up GPIO pins in Alternate Function (AF) mode. It is not thread-safe and must be called during the system initialization phase before the USB peripheral is enabled. It is generally not intended to be called from an ISR. A common mistake is calling this function after the USB peripheral has already started, which can cause electrical contention or signal integrity issues on the data lines.

Uso:

- This function is a mandatory step in the USB initialization sequence. It is typically called immediately after clock configuration and before the USB peripheral core is initialized via ca_usb_fs_dev_init. It ensures that the physical pins (D+, D-, and others like VBUS or ID) are correctly routed to the USB hardware block rather than acting as standard GPIOs.

Esempio:

```
/* Initialize USB Full-Speed GPIOs for the first USB peripheral */
ca_usb_fs_dev_gpio_init(0U);

/* Proceed to initialize the USB peripheral core */
/* ca_usb_fs_dev_init(0U); */

/* Connect the device to the USB bus */
ca_usb_connect();
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_fs_dev_gpio_init in my initialization sequence?
A: It must be called during the system initialization phase, specifically after clock configuration and before initializing the USB peripheral core via ca_usb_fs_dev_init.

Code example conf:1.00 **Q:** Provide a minimal C example for initializing USB GPIOs using caOS types.
A: u32 usb_index = 0U; ca_usb_fs_dev_gpio_init(usb_index);

Parameters conf:1.00 **Q:** What does the usb_num parameter represent in ca_usb_fs_dev_gpio_init?
A: It is the index of the USB peripheral to initialize (e.g., 0 for USB_OTG_FS1). The valid values depend on the specific MCU architecture being used.

Error/Edge case conf:1.00 **Q:** What happens if I call ca_usb_fs_dev_gpio_init after the USB peripheral has already started?
A: Calling it after the peripheral has started can cause electrical contention or signal integrity issues on the data lines.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_gpio_init thread-safe or ISR-safe?
A: The function is non-blocking, but it is not thread-safe and is generally not intended to be called from an ISR.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_gpio_init differ between STM32 H5xx and F4xx families?
A: On H5xx, the USB pins are dedicated and require no GPIO AF configuration, leaving them in reset state. On F4xx, the function performs explicit GPIO configuration and includes a specific workaround for boards with external D+ pull-ups by driving PA12 low to force a re-enumeration.

`ca_usb_fs_dev_init`

Header: `caos/drivers/inc/ca_glue_hw.h:33`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_usb_fs_dev_init(u32 usb_num, const ca_usb_cb_t *cb)
```

Initializes the USB Full-Speed hardware peripheral and registers the application callback structure.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to initialize (e.g., 0 for OTG_FS). Must be a valid hardware index for the specific MCU.
`cb`	`const ca_usb_cb_t *`	Pointer to a structure containing function pointers for USB events (e.g., reset, setup, data). Must not be NULL.

Ritorna:
Returns true if the hardware was successfully reset and configured, false if the initialization failed (e.g., invalid parameters or hardware timeout).

Note:

- This function performs low-level hardware initialization, including clock configuration, GPIO setup, and core reset. It is NOT thread-safe and must be called during the system startup phase before any USB communication begins. It is not intended to be called from an ISR. A common mistake is calling this function while the USB cable is already connected or before the required clocks are enabled, which can lead to hardware lockups or failed enumeration. Note that this function leaves the USB device in a disconnected state

(D+ pull-up disabled); you must call ca_usb_fs_dev_connect later to signal presence to the host.

Uso:

- This is the first step in the USB device lifecycle. It is typically called during system initialization after memory and clocks are configured. The sequence is: 1) ca_usb_fs_dev_init to prepare the hardware, 2) ca_usb_dev_mng_add to register endpoints, and 3) ca_usb_fs_dev_connect to physically signal the host that the device is ready for enumeration. It is paired with the callback structure that handles the USB protocol logic.

Esempio:

```c
/* Define the callback structure for USB events */
static const ca_usb_cb_t my_usb_callbacks = {
    /* .reset = my_reset_handler, .setup = my_setup_handler, ... */
};

void app_usb_init(void) {
    /* Initialize the USB FS peripheral (index 0) */
    if (ca_usb_fs_dev_init(0U, &my_usb_callbacks)) {
        /* Hardware ready, proceed to add endpoints and connect */
        /* ca_usb_dev_mng_add(...) */
        ca_usb_fs_dev_connect(0U);
    } else {
        ca_stdout_put_n("USB Init failed!\n");
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** What is the correct sequence to initialize the USB device in caOS?
A: The USB device lifecycle starts with ca_usb_fs_dev_init to configure hardware, followed by ca_usb_dev_mng_add to register endpoints, and finally ca_usb_fs_dev_connect to signal the host that the device is ready for enumeration.

Code example conf:0.90 **Q:** Provide a minimal C example for initializing the USB peripheral.
A: ca_usb_cb_t my_cbs = { .reset = my_reset_fn, .setup = my_setup_fn }; if (ca_usb_fs_dev_init(0, &my_cbs)) { /* proceed to register endpoints */ }

Parameters conf:1.00 **Q:** What are the requirements for the 'cb' parameter in ca_usb_fs_dev_init?
A: The 'cb' parameter must be a pointer to a ca_usb_cb_t structure containing function pointers for USB events. It must not be NULL, as the function will return false if it is.

Return conf:1.00 **Q:** What does a return value of false indicate from ca_usb_fs_dev_init?
A: A false return indicates that initialization failed. This can be caused by passing invalid parameters (like a NULL callback), or a hardware timeout during the core reset process (e.g., AHB idle or CSRST timeout).

Error/Edge case conf:1.00 **Q:** What is a common mistake that leads to hardware lockups during USB initialization?
A: A common mistake is calling ca_usb_fs_dev_init while the USB cable is already connected or before the required clocks are enabled, which can lead to hardware lockups or failed enumeration.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_init thread-safe or ISR-safe?
A: The function is not thread-safe and must be called during the system startup phase. It is not intended to be called from an ISR.

HW differences conf:1.00 **Q:** How does the USB initialization differ between H5xx and F4xx/F7xx families?
A: The H5xx family uses the USB_DRD_FS peripheral and manages power-down via the CNTR register (PDWN/USBRST bits), whereas F4xx, F7xx, and U5xx families use

the DWC2 OTG_FS core, which requires managing registers like GRSTCTL for core reset and GUSBCFG for PHY selection.

---

ca_usb_fs_dev_isr

Header: caos/drivers/inc/ca_glue_hw.h:39
GUARD: EN_CA_GLUE_HW

```
extern void ca_usb_fs_dev_isr(u32 usb_num)
```

Interrupt Service Routine (ISR) for the USB Full-Speed device peripheral.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral to service. Use 0 for single-USB devices; for multi-USB devices, refer to the specific hardware manual.

Ritorna:
void

Note:

- This function is an Interrupt Service Routine (ISR) and must be called exclusively from the hardware interrupt vector table associated with the USB peripheral. It is not thread-safe and must never be called from a standard task or thread context. Because it runs in interrupt context, it must execute as quickly as possible; avoid performing heavy processing or blocking operations inside this function. The most common mistake is attempting to use blocking caOS functions (like ca_os_delay or ca_mutex_lock) inside this ISR, which will cause system instability or deadlocks.

Uso:

- This function is the entry point for the USB hardware interrupt. It is typically registered in the startup vector table or the NVIC configuration. It handles low-level USB events such as bus resets, enumeration completion, and data packet reception by dispatching them to internal handler functions. It is the core of the USB stack's responsiveness; without it, the device will fail to communicate with the host or respond to enumeration requests.

Esempio:

```
/* Example of how the USB interrupt is linked to the system */

void USB_OTG_FS_IRQHandler(void)
{
    /* This is the hardware vector entry point */
    /* Call the caOS USB ISR handler for the first USB peripheral */
    ca_usb_fs_dev_isr(0);
}

/* Note: The internal handlers like handle_reset() or handle_rxflvl()
   are called internally by ca_usb_fs_dev_isr and are not part of the
   public caOS API. */
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call the ca_usb_fs_dev_isr function in my application?
A: You should not call this function manually from your application code. It is an Interrupt Service Routine (ISR) that must be registered in the hardware interrupt vector table or NVIC configuration to be triggered automatically by the USB peripheral hardware.

Code example conf:0.90 **Q:** How do I register the USB ISR in my startup code?
A: While the exact registration depends on your specific startup file, the function signature is: extern void ca_usb_fs_dev_isr(u32 usb_num);. For a single-USB device, you would typically map the USB interrupt vector to call ca_usb_fs_dev_isr(0);.

Parameters conf:1.00 **Q:** What does the u32 usb_num parameter represent?
A: The usb_num parameter is the index of the USB peripheral to service. Use 0 for single-USB devices. For multi-USB devices, you must refer to your specific hardware manual to determine the correct index.

Error/Edge case conf:1.00 **Q:** What happens if I call ca_os_delay inside ca_usb_fs_dev_isr?
A: Calling blocking caOS functions like ca_os_delay or ca_mutex_lock inside this ISR is a common mistake that will cause system instability or deadlocks, as the function must execute as quickly as possible and is not thread-safe.

Behavior conf:1.00 **Q:** Is ca_usb_fs_dev_isr thread-safe?
A: No, the function is not thread-safe. It is designed to run exclusively in an interrupt context and must never be called from a standard task or thread context.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_fs_dev_isr differ between the F1xx and F4xx families?
A: In the F1xx family, the implementation is essentially a stub that does nothing. In the F4xx family, the implementation is complex and directly interacts with the DWC2 USB_OTG_GlobalTypeDef registers (such as GINTSTS and GINTMSK) to handle specific events like bus resets, enumeration, and endpoint interrupts.

`ca_usb_fs_dev_set_address`

Header: `caos/drivers/inc/ca_glue_hw.h:37`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_usb_fs_dev_set_address(u32 usb_num, u8 addr)
```

Updates the USB device address in the hardware configuration register.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for FS, 1 for HS). Must be a valid peripheral index for the specific MCU.
`addr`	`u8`	The 7-bit USB address assigned by the host during enumeration. Valid range is 0 to 127.

Ritorna:
void

Note:

- This function is a low-level hardware abstraction layer (HAL) call. It is not thread-safe and should only be called by the USB stack's control transfer handler. On some architectures (like H5xx), the address update is deferred until the status stage of the control transfer is complete; calling this manually outside the stack's state machine will likely break USB enumeration. Do not call this from an ISR unless the specific hardware implementation explicitly supports it, as it modifies shared peripheral registers.

Uso:

- This function is used exclusively during the USB enumeration process when the host sends a 'Set Address' request. It is typically called by the USB stack after the device has

successfully received the address from the host and is ready to switch to the new address. It is usually paired with other USB stack functions that manage the control endpoint (EP0) state machine to ensure the address change happens at the correct protocol timing.

Esempio:

```
/* Example: Handling a Set Address request from the USB host */
void handle_usb_set_address(u32 usb_num, u8 new_addr)
{
    /* The USB stack has received the SET_ADDRESS request.
       We apply the address to the hardware peripheral. */
    ca_usb_fs_dev_set_address(usb_num, new_addr);

    /* After setting the address, we must ensure the status stage
       of the control transfer is acknowledged. */
    // ca_usb_fs_dev_ep_write(usb_num, 0, NULL, 0);
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_fs_dev_set_address in my USB stack implementation?
A: This function should be called exclusively during the USB enumeration process when the host sends a 'Set Address' request. It must be invoked by the USB stack's control transfer handler after the device has received the address and is ready to switch, ensuring it aligns with the protocol timing of the control endpoint (EP0) state machine.

Code example conf:1.00 **Q:** How do I correctly invoke the address update function in caOS?
A: You should call the function using the peripheral index and the 7-bit address provided by the host. Example: u32 usb_idx = 0; u8 new_addr = 0x05; ca_usb_fs_dev_set_address(usb_idx, new_addr);

Parameters conf:1.00 **Q:** What are the constraints on the 'addr' parameter for ca_usb_fs_dev_set_address?
A: The 'addr' parameter is a u8 representing the 7-bit USB address assigned by the host. The valid range is 0 to 127. Providing a value outside this range is not supported by the 7-bit addressing specification.

HW differences conf:1.00 **Q:** Are there architectural differences in how ca_usb_fs_dev_set_address handles the address update across MCU families?
A: Yes. On most families like F4xx, F7xx, H7xx, and U5xx, the function directly modifies the DCFG register of the DWC2 peripheral. However, on the H5xx family, the address update is deferred and stored in a state structure (g_st.pending_addr) to be applied only after the status stage of the control transfer is complete.

`ca_usb_get_speed`

Header: `caos/drivers/inc/usb.h:102`
Source: `caos/drivers/src/usb.c:67:71`
GUARD: `EN_USB`

```
ca_usb_speed_t ca_usb_get_speed(u32 usb_num)
```

Retrieves the current operational speed of the specified USB controller.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller to query. Must be less than USB_MAX_CTRL.

Ritorna:

Returns a ca_usb_speed_t enum value (e.g., CA_USB_SPEED_FS, CA_USB_SPEED_HS). Returns CA_USB_SPEED_FS as a default fallback if the provided index is invalid or the controller is not initialized.

Note:

- This function is non-blocking and thread-safe, as it performs a simple lookup in the internal driver table. It is safe to call from an ISR because it does not perform any complex operations or wait for hardware responses. The most common mistake is passing an uninitialized or out-of-bounds index, which will silently return the default Full-Speed (FS) value rather than an error code, potentially leading to incorrect timing assumptions in your USB stack logic.

Uso:

- This function is typically used during the USB enumeration process or when configuring endpoint buffers to determine if the hardware is operating at High-Speed (HS) or Full-Speed (FS). It is usually called after ca_usb_init and before opening endpoints with ca_usb_ep_open. Developers use it to dynamically adjust packet sizes or polling intervals based on the negotiated bus speed.

Esempio:

```c
/* Check USB speed before configuring endpoints */
u32 my_usb_id = 0;
ca_usb_speed_t speed = ca_usb_get_speed(my_usb_id);

if (speed == CA_USB_SPEED_HS) {
    /* High-speed logic: larger buffers might be needed */
    ca_printf("USB controller %u is running in High-Speed mode\n", my_usb_id);
} else {
    /* Full-speed logic */
    ca_printf("USB controller %u is running in Full-Speed mode\n", my_usb_id);
}

/* Proceed to open endpoints based on the detected speed */
// ca_usb_ep_open(my_usb_id, ...);
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_get_speed() and why would I need to know the USB speed?
A: You should call ca_usb_get_speed() when you need to determine the current speed of a USB connection, such as to optimize data transfer rates or to configure USB endpoints appropriately. Knowing the speed (Full-Speed or Low-Speed) helps in managing USB communication efficiently, especially when handling different device types or when debugging connection issues.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_usb_get_speed() with caOS types?
A: ca_usb_speed_t speed = ca_usb_get_speed(0); if (speed == CA_USB_SPEED_FULL) { // Handle Full-Speed USB connection } else if (speed == CA_USB_SPEED_LOW) { // Handle Low-Speed USB connection } else { // Handle unknown or disconnected USB }

Parameters conf:0.90 **Q:** What does the usb_num parameter represent, and what are valid values for it?
A: The usb_num parameter represents the identifier of the USB controller, where 0 typically refers to USB0 and 1 to USB1. Valid values are integers from 0 up to the maximum number of USB controllers available on the specific STM32 chip. Using negative values or values exceeding the maximum number of controllers can lead to undefined behavior.

Return conf:0.95 **Q:** What do the return values of ca_usb_get_speed() mean, and what causes each one?
A: CA_USB_SPEED_FULL indicates the USB connection is operating at 12 Mbps. CA_USB_SPEED_LOW indicates a 1.5 Mbps connection. CA_USB_SPEED_UNKNOWN means the speed has not been determined yet or the connection is absent, which can happen if the USB controller is not initialized or no device is connected.

`ca_usb_hs_dev_clock_init`

Header: `caos/drivers/inc/ca_glue_hw.h:48`
GUARD: `EN_CA_GLUE_HW`

```
extern void ca_usb_hs_dev_clock_init(u32 usb_num)
```

Initializes the hardware clock and power configuration for the High-Speed USB peripheral.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to initialize (e.g., 0 for USB_OTG_HS, 1 for USB_OTG_FS). Valid values are 0 or 1 depending on the specific STM32 hardware variant.

Ritorna:
void

Note:

- This function performs low-level register manipulation to enable the HSI48 oscillator and configure the USB clock source. It is a blocking function because it waits for the HSI48 oscillator to stabilize before returning. It is NOT thread-safe and must not be called from an ISR, as it performs busy-waiting loops. The most common mistake is calling this function before the system clock or power domains are properly initialized, which can lead to a system hang during the oscillator stabilization loop.

Uso:

- This function is typically the first step in the USB initialization sequence, called during the system boot phase or when a USB device is being brought online. It should be paired with subsequent hardware-specific initialization functions like ca_usb_hs_dev_gpio_init and ca_usb_hs_dev_init. It is used to ensure the peripheral has a valid clock signal before any USB communication or register access is attempted.

Esempio:

```
/* Initialize the USB High-Speed clock for the first USB peripheral */
ca_usb_hs_dev_clock_init(0U);

/* Proceed with GPIO and peripheral initialization */
/* ca_usb_hs_dev_gpio_init(0U); */
/* ca_usb_hs_dev_init(0U); */

/* Wait for USB connection to be established */
if (ca_usb_cdc_wait_connected(1000U)) {
    /* USB is ready for data transmission */
    ca_usb_cdc_write((u8 *)"USB Ready\r\n", 11U);
} else {
    /* Handle timeout or connection failure */
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_clock_init in my application?
A: It should be called during the system boot phase or when bringing a USB device online. It is the first step in the USB initialization sequence and must be called before any USB communication or register access, followed by functions like ca_usb_hs_dev_gpio_init and ca_usb_hs_dev_init.

Code example conf:1.00 **Q:** Provide a minimal example of how to initialize the USB clock using caOS types.
A: void init_usb(void) { u32 usb_index = 0; ca_usb_hs_dev_clock_init(usb_index); }

Parameters conf:1.00 **Q:** What does the usb_num parameter represent and what are the valid values?
A: The usb_num parameter is a u32 representing the index of the USB peripheral to initialize. Valid values are 0 (typically for USB_OTG_HS) or 1 (typically for USB_OTG_FS), depending on the specific STM32 hardware variant.

Error/Edge case conf:1.00 **Q:** Why might my system hang when calling ca_usb_hs_dev_clock_init?
A: The function performs a busy-waiting loop to wait for the HSI48 oscillator to stabilize. A common mistake is calling this function before the system clock or power domains are properly initialized, which causes the stabilization loop to hang.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_clock_init differ across STM32 families?
A: On the H7xx family, the function performs active register manipulation on RCC (e.g., RCC_CR_HSI48ON, RCC_D2CCIP2R) and PWR (PWR_CR3_USB33DEN) peripherals. In contrast, for the F1xx, F4xx, F7xx, H5xx, and U5xx families, the function is currently implemented as a stub that performs no operations, indicated by the (void)n cast.

`ca_usb_hs_dev_connect`

Header: `caos/drivers/inc/ca_glue_hw.h:57`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_usb_hs_dev_connect(u32 usb_num)
```

Connects the USB High-Speed device to the host by enabling the D+ pull-up resistor.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for USB_OTG_HS). Must be a valid index supported by the hardware.

Ritorna:
void

Note:

- This function is non-blocking and performs a direct register write to the USB controller's Device Control Register (DCTL) to clear the Soft Disconnect (SDIS) bit. It is not thread-safe in the sense that it should only be called once the USB device stack is fully initialized and ready to handle enumeration requests from the host. Calling this too early will cause the host to detect the device before the firmware is ready, leading to enumeration failures or 'Device Descriptor Request Failed' errors. It is not intended to be called from an ISR, as it is part of the high-level device management sequence.

Uso:

- This function is the final step in the USB device initialization sequence. It is typically called after the USB hardware has been clocked, the GPIOs configured, and all endpoints have been opened using ca_usb_hs_dev_ep_open. It is usually invoked by the higher-level management function ca_usb_dev_mng_start to signal to the host that the device is ready to begin the enumeration process. Do not call this function until your application is prepared to handle the subsequent setup packets from the host.

Esempio:

```c
/* Example of initializing a USB device and connecting it to the host */
void start_usb_device(u32 usb_num) {
    /* 1. Initialize hardware and clocks (platform specific) */
    ca_usb_hs_dev_clock_init(usb_num);
    ca_usb_hs_dev_gpio_init(usb_num);

    /* 2. Open necessary endpoints for communication */
    /* Endpoint 0 is mandatory for control transfers */
    ca_usb_hs_dev_ep_open(usb_num, 0x00, USB_EP_TYPE_CONTROL, 64);
    ca_usb_hs_dev_ep_open(usb_num, 0x81, CA_USB_EP_TYPE_BULK, 512);

    /* 3. Finalize setup and connect to host */
    /* This enables the D+ pull-up, triggering host enumeration */
    ca_usb_hs_dev_connect(usb_num);

    /* Now the device is visible to the host */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** At what point in the USB initialization sequence should I call ca_usb_hs_dev_connect?
A: It should be the final step in the initialization sequence, called only after the USB hardware is clocked, GPIOs are configured, and all endpoints have been opened via ca_usb_hs_dev_ep_open. It is typically invoked by ca_usb_dev_mng_start to signal the host that the device is ready for enumeration.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to connect the USB device using caOS types.
A: u32 usb_idx = 0U; /* Initialize hardware and endpoints first */ ca_usb_hs_dev_connect(usb_idx);

Parameters conf:0.90 **Q:** What does the usb_num parameter represent and what are valid values?
A: The usb_num parameter is the index of the USB peripheral (e.g., 0 for USB_OTG_HS). It must be a valid index supported by the hardware; for example, in the H7 implementation, the index must be less than 2.

Error/Edge case conf:1.00 **Q:** What happens if I call ca_usb_hs_dev_connect before the firmware is fully ready?
A: Calling it too early causes the host to detect the device before the firmware is prepared to handle setup packets, which leads to enumeration failures or 'Device Descriptor Request Failed' errors.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_connect thread-safe or ISR-safe?
A: The function is non-blocking and performs a direct register write. It is not thread-safe and is not intended to be called from an ISR, as it is part of the high-level device management sequence.

HW differences conf:0.90 **Q:** How does the implementation of ca_usb_hs_dev_connect differ across MCU families?
A: In the H7xx family, the function explicitly clears the SDIS bit in the DCTL register of the DWC2 peripheral. In other families like F1xx, F4xx, F7xx, H5xx, and U5xx, the provided implementation is currently a stub that performs no register operations.

ca_usb_hs_dev_disconnect

Header: caos/drivers/inc/ca_glue_hw.h:58
GUARD: EN_CA_GLUE_HW

```
extern void ca_usb_hs_dev_disconnect(u32 usb_num)
```

Forces a USB High-Speed device to disconnect by setting the Soft Disconnect bit in the hardware controller.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB High-Speed peripheral (e.g., 0 or 1). Values outside the supported hardware range (typically >= 2) are ignored.

Ritorna:
void

Note:

- This function is non-blocking and performs a direct register write to the USB controller's DCTL register. It is thread-safe in the sense that it performs an atomic register modification, but it does not provide synchronization with the USB stack state. It is safe to call from an ISR, as it does not involve any OS primitives or blocking waits. The most common mistake is calling this function while the USB stack is actively transmitting data, which can lead to unexpected behavior or incomplete transfers; ensure the stack is in a quiescent state before disconnecting.

Uso:

- This function is used to programmatically simulate a physical cable unplug event, which is useful for forcing a re-enumeration of the USB device by the host. It is typically paired with ca_usb_hs_dev_connect to reset the connection after a configuration change or a firmware-level reset. In a typical lifecycle, you would call this to drop the connection, perform necessary hardware re-initialization, and then call the connect function to signal the host to re-enumerate the device.

Esempio:

```
/* Example: Force a USB re-enumeration */

void reset_usb_connection(u32 usb_id) {
    /* Disconnect the device from the host */
    ca_usb_hs_dev_disconnect(usb_id);

    /* Wait for a short period to ensure the host detects the disconnect */
    ca_os_delay_ms(100);

    /* Re-connect the device to trigger re-enumeration */
    ca_usb_hs_dev_connect(usb_id);
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_usb_hs_dev_disconnect and what is its primary purpose?
A: You should use this function to programmatically simulate a physical USB cable unplug event. It is primarily used to force a re-enumeration of the USB device by

the host, often paired with ca_usb_hs_dev_connect after a configuration change or firmware-level reset. Ensure the USB stack is in a quiescent state before calling it to avoid incomplete transfers.

Code example conf:1.00 **Q:** How do I implement a soft reset of the USB connection in caOS?
A: You can perform a reset by disconnecting and then reconnecting the device: ca_usb_hs_dev_disconn /* Perform re-init */ ca_usb_hs_dev_connect(0);

Parameters conf:1.00 **Q:** What are the valid values for the usb_num parameter in ca_usb_hs_dev_disconnect?
A: The usb_num parameter represents the index of the USB High-Speed peripheral. Valid values are typically 0 or 1. Any value outside the supported hardware range (typically >= 2) is ignored by the function.

HW differences conf:1.00 **Q:** Are there differences in how ca_usb_hs_dev_disconnect is implemented across different STM32 families?
A: Yes. For the H7xx family, the function performs a direct register write to the DCTL register (setting the USB_OTG_DCTL_SDIS bit) for valid indices. In contrast, for the F1xx, F4xx, F7xx, H5xx, and U5xx families, the provided implementation is a stub that performs no operation, meaning the function does not currently control hardware on those specific platforms.

`ca_usb_hs_dev_ep_clear_stall`

Header: `caos/drivers/inc/ca_glue_hw.h:61`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_usb_hs_dev_ep_clear_stall(u32 usb_num, u8 ep_addr)
```

Clears the STALL condition on a specific USB High-Speed endpoint and resets its data toggle.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for USB_OTG_HS). Must be less than 2.
`ep_addr`	`u8`	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Must be a valid endpoint index.

Ritorna:
Returns true if the stall was successfully cleared, false if the parameters were invalid or the hardware does not support this operation.

Note:

- This function is non-blocking and executes immediately by modifying hardware registers. It is thread-safe regarding the USB state structure, but it should be used carefully as it resets the data toggle (PID) to DATA0, which can cause synchronization issues if the host is not expecting a reset. It is not intended to be called from an ISR unless the specific hardware implementation guarantees atomicity, which is generally not the case for complex USB register sequences. The most common beginner mistake is calling this function when the endpoint is not actually stalled, which may force an unnecessary data toggle reset and lead to packet sequence errors.

Uso:

- This function is typically used in the USB device stack error recovery sequence. When a host sends a request that the device cannot process, the device may respond with a

STALL; once the error condition is resolved, the host sends a 'Clear Feature' request, which triggers this function. It is usually paired with ca_usb_hs_dev_ep_stall to manage endpoint states and is called after the USB stack has successfully processed the control transfer that requested the stall clearance.

Esempio:

```c
/* Assuming we need to recover endpoint 1 after a protocol error */
u8 ep_addr = 0x81; // Endpoint 1 IN
u32 usb_idx = 0;

/* Clear the stall condition on the hardware */
if (ca_usb_hs_dev_ep_clear_stall(usb_idx, ep_addr)) {
    /* Successfully cleared, now we can resume normal data transmission */
    /* ca_usb_hs_dev_ep_write(usb_idx, ep_addr, buffer, size); */
} else {
    /* Handle error: invalid endpoint or hardware failure */
    ca_printf("Failed to clear stall on EP 0x%02X\n", ep_addr);
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_ep_clear_stall in my USB device stack?
A: This function is typically used during the USB device stack error recovery sequence. It should be called after the host sends a 'Clear Feature' request to resolve an error condition that previously caused the device to issue a STALL.

Code example conf:1.00 **Q:** Provide a minimal example of clearing a stall on endpoint 1 IN.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; if (ca_usb_hs_dev_ep_clear_stall(usb_idx, ep_addr)) { /* Success */ }

Parameters conf:1.00 **Q:** What are the constraints for the usb_num and ep_addr parameters?
A: usb_num must be less than 2 (e.g., 0 for USB_OTG_HS). ep_addr must be a valid endpoint address, such as 0x81 for IN endpoint 1 or 0x02 for OUT endpoint 2.

Return conf:1.00 **Q:** What do the return values of ca_usb_hs_dev_ep_clear_stall indicate?
A: It returns true if the stall was successfully cleared. It returns false if the parameters provided are invalid (e.g., usb_num >= 2 or invalid endpoint index) or if the hardware does not support this operation.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using this function?
A: The most common beginner mistake is calling this function when the endpoint is not actually stalled. This forces an unnecessary data toggle reset to DATA0, which can lead to packet sequence errors if the host is not expecting it.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_ep_clear_stall safe to call from an ISR or concurrently?
A: The function is non-blocking and thread-safe regarding the USB state structure. However, it is not intended to be called from an ISR because the complex USB register sequences involved are generally not atomic.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_ep_clear_stall vary across STM32 families?
A: For F1xx, F4xx, F7xx, H5xx, and U5xx families, the function is a stub that returns false and performs no action. Only the H7xx implementation contains the logic to modify DWC2 registers (DIEPCTL/DOEPCTL) and reset data toggles for BULK/INTR endpoints.

`ca_usb_hs_dev_ep_close`

Header: `caos/drivers/inc/ca_glue_hw.h:60`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_usb_hs_dev_ep_close(u32 usb_num, u8 ep_addr)
```

Closes a specific USB High-Speed device endpoint and resets its internal driver state.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (0 or 1). Values >= 2 are invalid.
ep_addr	u8	The endpoint address (e.g., 0x81 for IN endpoint 1). Endpoint 0 cannot be closed.

Ritorna:

Returns true if the endpoint was successfully closed, false if the endpoint was already closed, invalid, or if the index is out of range.

Note:

- This function is blocking because it performs hardware-level handshaking (SNAK/EPDIS) and waits for hardware status bits to clear, which can take time depending on bus traffic. It is NOT safe to call from an ISR because it uses busy-wait loops (DWC2_WAIT). You must ensure the endpoint was previously opened via ca_usb_hs_dev_ep_open before calling this. A common mistake is attempting to close Endpoint 0, which is reserved for control transfers and managed by the stack, or calling this while the USB bus is under heavy load, which might trigger the internal timeout.

Uso:

- This function is typically used during USB device reconfiguration, such as when a host sends a 'Set Configuration' request that changes the active interface or alternate setting. It is part of the cleanup sequence: first, you stop data transmission, then you call ca_usb_hs_dev_ep_close to release the hardware resources, and finally, you may re-open the endpoint with different parameters if needed. It is the counterpart to ca_usb_hs_dev_ep_open.

Esempio:

```
/* Example: Closing an endpoint during a configuration change */
#define EP_IN_1 0x81

void handle_usb_reconfig(u32 usb_idx) {
    /* Ensure we are not currently transmitting before closing */
    /* Assume a hypothetical check function exists */
    if (/* check if EP_IN_1 is busy */ false) {
        /* Wait for completion or abort */
    }

    /* Close the endpoint to free hardware resources */
    if (ca_usb_hs_dev_ep_close(usb_idx, EP_IN_1)) {
        /* Successfully closed, now we can re-initialize or stay idle */
    } else {
        /* Handle error: endpoint was already closed or invalid */
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_ep_close in my USB stack implementation?

A: You should call it during USB device reconfiguration, such as when the host sends a 'Set Configuration' request that changes the active interface or alternate setting. It is used to release hardware resources after stopping data transmission, often as a cleanup step before re-opening the endpoint with different parameters.

Code example conf:1.00 **Q:** Provide a minimal example of how to close an IN endpoint using caOS types.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; if (ca_usb_hs_dev_ep_close(usb_idx, ep_addr)) { /* Endpoint closed successfully */ }

Parameters conf:1.00 **Q:** What are the constraints on the ep_addr parameter?
A: The ep_addr represents the endpoint address (e.g., 0x81 for IN endpoint 1). Endpoint 0 is reserved for control transfers and cannot be closed using this function. Additionally, the endpoint must have been previously opened via ca_usb_hs_dev_ep_open.

Return conf:1.00 **Q:** What does a return value of false indicate?
A: A return value of false indicates that the endpoint was already closed, the provided endpoint address is invalid, the USB peripheral index is out of range (>= 2), or an attempt was made to close the reserved Endpoint 0.

Error/Edge case conf:1.00 **Q:** Why might ca_usb_hs_dev_ep_close fail during heavy bus traffic?
A: The function performs hardware-level handshaking (SNAK/EPDIS) and uses busy-wait loops (DWC2_WAIT) to monitor hardware status bits. If the USB bus is under heavy load, the hardware may not respond within the internal timeout period, causing the operation to fail.

Behavior conf:1.00 **Q:** Is it safe to call ca_usb_hs_dev_ep_close from an interrupt service routine (ISR)?
A: No, it is not safe. The function is blocking and utilizes busy-wait loops (DWC2_WAIT) to perform hardware handshaking, which can take significant time depending on bus traffic.

HW differences conf:1.00 **Q:** Are there differences in the implementation of ca_usb_hs_dev_ep_close across STM32 families?
A: Yes. While the function signature is consistent, the H7xx family provides a full implementation using DWC2 registers (e.g., DIEPCTL, DOEPCTL, GINTSTS, DCTL) to manage hardware handshaking and FIFO flushing. Conversely, the F1xx, F4xx, F7xx, H5xx, and U5xx families currently provide stub implementations that return false and perform no operations.

`ca_usb_hs_dev_ep_is_stalled`

Header: `caos/drivers/inc/ca_glue_hw.h:62`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_usb_hs_dev_ep_is_stalled(u32 usb_num, u8 ep_addr)
```

Checks if a specific USB High-Speed device endpoint is currently in a stalled state.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 or 1). Must be within the valid range for the specific MCU.
`ep_addr`	`u8`	The endpoint address (e.g., 0x81 for IN endpoint 1, 0x02 for OUT endpoint 2). Must be a valid endpoint number for the hardware.

Ritorna:
Returns true if the endpoint is stalled, false if it is not stalled or if the parameters are invalid (e.g., out-of-bounds index).

Note:

- This function is non-blocking and thread-safe as it performs a direct register read. It is safe to call from an ISR because it does not involve OS primitives or waiting. The function relies on the underlying hardware registers (DWC2 on H7xx); on many other STM32 series, this function is currently unimplemented and will always return false. A common mistake is assuming this function will work on all STM32 platforms; always check the specific hardware implementation file for your target.

Uso:

- This function is typically used during USB error recovery or protocol debugging to determine why data transfers are failing. It is often paired with ca_usb_hs_dev_ep_clear_stall to reset an endpoint after a protocol error has been resolved. Developers use this to verify the state of the USB stack after receiving a stall condition from the host or after a local error event.

Esempio:

```c
/* Check if endpoint 1 IN is stalled before attempting to clear it */
#define EP_IN_1 0x81

void check_and_recover_usb(u32 usb_idx) {
    if (ca_usb_hs_dev_ep_is_stalled(usb_idx, EP_IN_1)) {
        /* Endpoint is stalled, attempt to clear the stall condition */
        /* Call the function to clear the stall bit in the hardware register */
        ca_usb_hs_dev_ep_clear_stall(usb_idx, EP_IN_1);
    } else {
        /* Endpoint is healthy, proceed with normal data transmission */
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_usb_hs_dev_ep_is_stalled in my application?
A: This function is typically used during USB error recovery or protocol debugging to investigate why data transfers are failing. It is often paired with ca_usb_hs_dev_ep_clear_stall to reset an endpoint after a protocol error has been resolved or to verify the endpoint state after receiving a stall condition from the host.

Code example conf:1.00 **Q:** How do I check if endpoint 0x81 is stalled on USB peripheral 0?
A: You can call the function directly as shown: bool stalled = ca_usb_hs_dev_ep_is_stalled(0U, 0x81U); if (stalled) { /* handle stall */ }

Parameters conf:1.00 **Q:** What are the requirements for the ep_addr parameter?
A: The ep_addr parameter must be a valid endpoint address for the hardware, such as 0x81 for IN endpoint 1 or 0x02 for OUT endpoint 2. The function internally extracts the endpoint number and direction; providing an invalid endpoint number will result in the function returning false.

Return conf:1.00 **Q:** What does a return value of false indicate?
A: A return value of false indicates that the endpoint is not currently in a stalled state, or that the parameters provided (such as usb_num or ep_addr) were invalid/out-of-bounds. On many STM32 series where this function is unimplemented, it will also consistently return false.

HW differences conf:1.00 **Q:** Why does ca_usb_hs_dev_ep_is_stalled return false on my F4xx device?
A: The function relies on DWC2 hardware registers (specifically DIEPCTL and DOEPCTL) which are implemented for the H7xx family. For many other STM32 series, including F1xx, F4xx, F7xx, H5xx, and U5xx, the function is currently unimplemented and explicitly returns false regardless of the actual hardware state.

ca_usb_hs_dev_ep_open

Header: caos/drivers/inc/ca_glue_hw.h:51
GUARD: EN_CA_GLUE_HW

```
extern bool ca_usb_hs_dev_ep_open(u32 usb_num, u8 ep_addr,
    ca_usb_ep_type_t type, u16 mps)
```

Configures and enables a specific USB High-Speed device endpoint for data transmission or reception.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (0 or 1). Values >= 2 are invalid.
ep_addr	u8	The endpoint address (e.g., 0x81 for IN, 0x02 for OUT). Must be within valid hardware limits.
type	ca_usb_ep_type_t	The transfer type (Control, Bulk, Interrupt, or Isochronous).
mps	u16	Maximum Packet Size in bytes. Must match the descriptor requirements.

Ritorna:
Returns true if the endpoint was successfully configured, false if the parameters are invalid or the hardware is not supported.

Note:

- This function is non-blocking and performs direct register manipulation on the USB OTG peripheral. It is not thread-safe; ensure that endpoint configuration is performed during the initialization phase or within a protected context to avoid race conditions. It is not intended to be called from an ISR. A common mistake is providing an endpoint address that exceeds the hardware's maximum endpoint count or failing to ensure the USB peripheral clock is initialized before calling this function.

Uso:

- This function is typically used during the USB device enumeration process after the USB peripheral has been initialized via ca_usb_hs_dev_init. It is called for each endpoint defined in the device's configuration descriptor to prepare the hardware registers for data flow. It is usually paired with ca_usb_hs_dev_ep_write or ca_usb_hs_dev_ep_read to handle actual data transfers once the host has configured the device.

Esempio:

```
/* Example: Opening a Bulk IN endpoint (0x81) with 512 bytes MPS */
#define EP_BULK_IN 0x81

void setup_usb_endpoints(u32 usb_idx) {
    /* Configure endpoint 1 as Bulk IN with 512 bytes MPS */
    bool success = ca_usb_hs_dev_ep_open(usb_idx, EP_BULK_IN,
    CA_USB_EP_TYPE_BULK, 512);

    if (!success) {
        /* Handle configuration error: log or enter safe state */
        ca_printf("Failed to open USB endpoint!\n");
    } else {
        ca_printf("Endpoint 0x81 opened successfully.\n");
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_ep_open in my application?
A: This function is typically called during the USB device enumeration process, after the USB peripheral has been initialized via ca_usb_hs_dev_init. It should be invoked for each endpoint defined in the device's configuration descriptor to prepare the hardware registers for data flow.

Code example conf:0.90 **Q:** Provide a minimal example of how to open a Bulk IN endpoint using caOS types.
A: u32 usb_idx = 0; u8 ep_addr = 0x81; ca_usb_ep_type_t type = CA_USB_EP_BULK; u16 mps = 64; bool success = ca_usb_hs_dev_ep_open(usb_idx, ep_addr, type, mps);

Parameters conf:1.00 **Q:** What are the constraints on the usb_num and ep_addr parameters?
A: The usb_num parameter must be 0 or 1; values >= 2 are invalid. The ep_addr must be within valid hardware limits for the specific MCU, and the endpoint index derived from it must be less than USB_EP_MAX.

Return conf:1.00 **Q:** What do the return values of ca_usb_hs_dev_ep_open indicate?
A: It returns true if the endpoint was successfully configured. It returns false if the parameters are invalid (e.g., invalid usb_num or ep_addr) or if the hardware is not supported.

Error/Edge case conf:1.00 **Q:** What are some common mistakes when using ca_usb_hs_dev_ep_open?
A: Common mistakes include providing an endpoint address that exceeds the hardware's maximum endpoint count, or failing to ensure the USB peripheral clock is initialized before calling the function.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_ep_open thread-safe or ISR-safe?
A: The function is non-blocking but not thread-safe; it must be called during initialization or within a protected context to avoid race conditions. It is not intended to be called from an ISR.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_ep_open differ across MCU families?
A: For the H7xx family, the function performs direct register manipulation on the DWC2 peripheral (e.g., DIEPCTL, DOEPCTL, and DAINTMSK). In contrast, for F1xx, F4xx, F7xx, H5xx, and U5xx families, the provided implementation is a stub that returns false, indicating the driver is not yet implemented for those specific families.

`ca_usb_hs_dev_ep_read`

Header: `caos/drivers/inc/ca_glue_hw.h:53`
GUARD: `EN_CA_GLUE_HW`

```
extern u16 ca_usb_hs_dev_ep_read(u32 usb_num, u8 ep_addr, u8 *buf, u16
    max_len)
```

Reads received data from a specific USB High-Speed device endpoint into a provided buffer.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	Index of the USB peripheral (0 or 1). Must be valid for the hardware configuration.
ep_addr	u8	Endpoint address (e.g., 0x01 for EP1 OUT). Must be an OUT endpoint; IN endpoints will return 0.
buf	u8 *	Pointer to the destination buffer where data will be copied. Must not be NULL.
max_len	u16	Maximum number of bytes to copy. If the received packet is larger, only this amount is copied.

Ritorna:
Returns the number of bytes actually copied into the buffer. Returns 0 if the endpoint is empty, the parameters are invalid, or the endpoint is an IN type.

Note:

- This function is non-blocking and thread-safe for EP1+ as it uses a ring buffer mechanism. It is NOT safe to call from an ISR because it manages critical sections and internal state updates that must be synchronized with the main task context. A common mistake is passing an IN endpoint address or a NULL buffer, which will immediately return 0. Ensure the endpoint has been successfully opened via ca_usb_hs_dev_ep_open before attempting to read, otherwise the internal state will not be ready to receive data.

Uso:

- This function is typically used within a task loop or a callback triggered by a USB event. The standard sequence is: 1) Initialize the USB peripheral, 2) Open the desired endpoint using ca_usb_hs_dev_ep_open, 3) Periodically poll or wait for a signal indicating data availability, 4) Call ca_usb_hs_dev_ep_read to retrieve the data into a local buffer, and 5) Process the data. It is often paired with ca_usb_hs_dev_ep_write to send responses back to the host.

Esempio:

```
u8 rx_buffer[64];
u16 bytes_received;

/* Assuming USB peripheral 0 and EP1 OUT (0x01) are already initialized and
    opened */
bytes_received = ca_usb_hs_dev_ep_read(0, 0x01, rx_buffer, sizeof(rx_buffer));

if (bytes_received > 0) {
    /* Data successfully copied to rx_buffer, process it here */
    ca_printf("Received %d bytes\n", bytes_received);
} else {
    /* No data available or error occurred */
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** What is the standard workflow for reading data from a USB endpoint in caOS?
A: The standard sequence is: 1) Initialize the USB peripheral, 2) Open the desired endpoint using ca_usb_hs_dev_ep_open, 3) Periodically poll or wait for a signal indicating data availability, 4) Call ca_usb_hs_dev_ep_read to retrieve the data into a local buffer, and 5) Process the data.

Code example conf:1.00 **Q:** Provide a minimal C example of reading data from USB endpoint 1.

A: u8 buffer[64]; u16 bytes_read = ca_usb_hs_dev_ep_read(0, 0x01, buffer, 64); if (bytes_read > 0) { /* Process data */ }

Parameters conf:1.00 **Q:** What are the constraints on the ep_addr and buf parameters?

A: ep_addr must be an OUT endpoint; IN endpoints will return 0. The buf parameter must be a non-NULL pointer to a destination buffer.

Return conf:1.00 **Q:** What does the return value of ca_usb_hs_dev_ep_read represent?

A: It returns the number of bytes actually copied into the buffer. It returns 0 if the endpoint is empty, the parameters are invalid, or the endpoint is an IN type.

Error/Edge case conf:1.00 **Q:** What are common mistakes that cause ca_usb_hs_dev_ep_read to return 0?

A: Common mistakes include passing an IN endpoint address, providing a NULL buffer, or attempting to read from an endpoint that has not been successfully opened via ca_usb_hs_dev_ep_open.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_ep_read safe to call from an ISR?

A: No, it is not safe to call from an ISR because it manages critical sections and internal state updates that must be synchronized with the main task context.

HW differences conf:1.00 **Q:** How does the H7 implementation handle EP0 versus EP1+?

A: On H7, EP0 uses legacy single staging where data is read from a DMA buffer, while EP1+ uses a dedicated RX ring buffer mechanism that allows for non-blocking, thread-safe access by the consumer task.

`ca_usb_hs_dev_ep_stall`

Header: `caos/drivers/inc/ca_glue_hw.h:59`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_usb_hs_dev_ep_stall(u32 usb_num, u8 ep_addr)
```

Forces a USB endpoint into a STALL state to signal a protocol error or unsupported request to the host.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for USB_OTG_HS). Must be a valid peripheral index supported by the hardware.
`ep_addr`	`u8`	The endpoint address. Bit 7 is the direction (1 for IN, 0 for OUT). Bits 0-3 represent the endpoint number.

Ritorna:
void

Note:

- This function is non-blocking and executes immediately by modifying the hardware control registers. It is thread-safe in the sense that it performs atomic register writes, but it should be used carefully to avoid race conditions with the USB interrupt service routine. It is safe to call from an ISR, but typically it is called from the main USB stack logic when a request cannot be fulfilled. A common mistake is passing an invalid endpoint address or an endpoint number that has not been opened, which may lead to undefined behavior or ignored commands by the USB controller.

Uso:

- This function is used during USB enumeration or data transfer phases when the device receives a request it cannot handle (e.g., an unsupported standard request or a buffer overflow condition). It is typically paired with 'ca_usb_hs_dev_ep_open' during initialization and 'ca_usb_hs_dev_ep_clear_stall' when the host clears the stall condition. In a standard USB stack flow, you would call this when the control transfer state machine enters an error state, signaling the host that the specific endpoint is temporarily unable to process further traffic.

Esempio:

```
/* Example: Handling an unsupported request on Endpoint 1 IN */
#define EP1_IN_ADDR 0x81U

void handle_usb_request(u8 request_type) {
    if (request_type == 0xFFU) {
        /* Unsupported request: Stall the endpoint to notify the host */
        ca_usb_hs_dev_ep_stall(0, EP1_IN_ADDR);
    } else {
        /* Proceed with normal data processing */
        // ca_usb_hs_dev_ep_write(0, EP1_IN_ADDR, buffer, size);
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_ep_stall in my USB stack?
A: You should call this function when the device receives a request it cannot handle, such as an unsupported standard request or a buffer overflow condition. It is typically used during USB enumeration or data transfer phases to signal to the host that a specific endpoint is temporarily unable to process further traffic.

Code example conf:1.00 **Q:** How do I implement a stall on endpoint 1 IN using caOS types?
A: You can trigger the stall by calling the function with the peripheral index and the endpoint address (where bit 7 is set for IN). Example: u32 usb_idx = 0; u8 ep_addr = 0x81; ca_usb_hs_dev_ep_stall(usb_idx, ep_addr);

Parameters conf:1.00 **Q:** How is the ep_addr parameter formatted for ca_usb_hs_dev_ep_stall?
A: The ep_addr parameter is an u8 where bits 0-3 represent the endpoint number, and bit 7 indicates the direction (1 for IN, 0 for OUT). Passing an invalid endpoint address or an endpoint that has not been opened may lead to undefined behavior or ignored commands.

HW differences conf:1.00 **Q:** Are there differences in how ca_usb_hs_dev_ep_stall is implemented across STM32 families?
A: Yes. For the H7xx family, the function actively modifies hardware registers (DWC2_EPIN/DWC2_E DIEPCTL/DOEPCTL bits) and includes logic to re-arm endpoint 0. In contrast, for the F1xx, F4xx, F7xx, H5xx, and U5xx families, the provided implementation is a stub that performs no action.

`ca_usb_hs_dev_ep_write`

Header: `caos/drivers/inc/ca_glue_hw.h:52`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_usb_hs_dev_ep_write(u32 usb_num, u8 ep_addr, const u8 *
    buf, u16 len)
```

Queues data for transmission on a specific USB High-Speed device endpoint.

Parametri:

Nome	Tipo	Descrizione
usb_num	u32	The index of the USB peripheral (usually 0 or 1).
ep_addr	u8	The endpoint address (e.g., 0x81 for IN endpoint 1). Must be an IN endpoint.
buf	const u8 *	Pointer to the data buffer to send. Must be valid for the duration of the transfer.
len	u16	Number of bytes to send. Must not exceed the endpoint's buffer capacity.

Ritorna:
Returns true if the data was successfully queued for transmission, false otherwise (e.g., invalid endpoint, buffer full, or hardware busy).

Note:

- This function is non-blocking; it copies data into an internal ring buffer and returns immediately. It is thread-safe for EP1+ because it manages its own internal queue, but it is NOT safe to call from an ISR. A common mistake is assuming the data has been physically sent the moment the function returns; the actual transmission happens asynchronously via the USB hardware engine. Ensure the endpoint is properly opened with ca_usb_hs_dev_ep_open before calling this function.

Uso:

- This function is used in the main data transmission loop of a USB device application. It is typically paired with ca_usb_hs_dev_ep_open to initialize the endpoint and ca_usb_hs_dev_connect to start the USB communication. In a typical sequence, you initialize the USB stack, open the required endpoints, and then call this function whenever you have data ready to be sent to the host.

Esempio:

```c
/* Example: Sending data over USB High-Speed Endpoint 1 */
#define EP1_IN 0x81

void send_usb_data(const u8 *data, u16 length) {
    /* Ensure the USB endpoint is ready before writing */
    if (ca_usb_hs_dev_ep_write(0, EP1_IN, data, length)) {
        /* Data successfully queued in the internal ring buffer */
    } else {
        /* Handle error: queue full or invalid endpoint */
        ca_printf("USB write failed!\n");
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_ep_write in my application?
A: You should call this function in your main data transmission loop whenever you have data ready to be sent to the host. It must be called after the USB stack is initialized, the specific endpoint is opened with ca_usb_hs_dev_ep_open, and the USB connection is established via ca_usb_hs_dev_connect.

Code example conf:1.00 **Q:** Provide a minimal example of how to send data using ca_usb_hs_dev_ep_write.
A: u8 data[] = {0x01, 0x02, 0x03}; u32 usb_idx = 0; u8 ep = 0x81; if (ca_usb_hs_dev_ep_write(usb_i
ep, data, 3)) { /* Data queued successfully */ }

Parameters conf:1.00 **Q:** What are the requirements for the ep_addr and len parameters?
A: The ep_addr must represent an IN endpoint (e.g., 0x81). The len parameter specifies the number of bytes to send and must not exceed the capacity of the endpoint's buffer.

Return conf:1.00 **Q:** What does a return value of false indicate when calling ca_usb_hs_dev_ep_write?
A: A return value of false indicates that the data could not be queued. This can happen if the endpoint address is invalid, the internal buffer is full, the hardware is busy, or the endpoint was not properly opened.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make regarding the timing of data transmission?
A: A common mistake is assuming the data has been physically sent to the host the moment the function returns. The function is non-blocking and only queues the data; the actual transmission occurs asynchronously via the USB hardware engine.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_ep_write safe to call from an Interrupt Service Routine (ISR)?
A: No, it is not safe to call this function from an ISR. While it is thread-safe for endpoints EP1 and higher due to internal queue management, it is strictly non-blocking and relies on mechanisms not suitable for ISR context.

HW differences conf:1.00 **Q:** Are there differences in the implementation of ca_usb_hs_dev_ep_write across STM32 families?
A: Yes. While the function signature is consistent, the H7xx implementation contains specific logic for managing TX ring buffers, DMA, and DWT latency tracking, whereas the F1xx, F4xx, F7xx, H5xx, and U5xx implementations provided in the documentation are currently stubs that return false.

`ca_usb_hs_dev_get_speed`

Header: `caos/drivers/inc/ca_glue_hw.h:55`
GUARD: `EN_CA_GLUE_HW`

```
1 extern ca_usb_speed_t ca_usb_hs_dev_get_speed(u32 usb_num)
```

Retrieves the current operational speed of the specified High-Speed USB device controller.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to query. Valid values are typically 0 or 1 depending on the specific STM32 hardware configuration.

Ritorna:
Returns a ca_usb_speed_t enum value (e.g., CA_USB_SPEED_HS, CA_USB_SPEED_FS). If the index is invalid, it may return a default value like CA_USB_SPEED_FS depending on the specific hardware implementation.

Note:

- This function is non-blocking and thread-safe as it typically performs a simple register read or returns a cached value from the USB driver state. It is safe to call from an ISR, provided the hardware index is valid. The primary precondition is that the USB peripheral must have been initialized via the appropriate driver init function. A common mistake is passing an out-of-bounds index, which can lead to undefined behavior or return a default speed value that does not match the actual hardware capability.

Uso:

- This function is used during the USB enumeration process or when diagnosing connection issues to verify if the device has successfully negotiated High-Speed (HS) or Full-Speed (FS) mode. It is typically called after the USB stack has been initialized and the device

has been connected to a host. It is often paired with ca_usb_hs_dev_init to ensure the peripheral is ready before querying its status.

Esempio:

```c
/* Check the speed of the first USB HS controller */
u32 usb_index = 0;
ca_usb_speed_t speed = ca_usb_hs_dev_get_speed(usb_index);

if (speed == CA_USB_SPEED_HS) {
    /* Device is operating at High Speed */
    ca_printf("USB device %u is running at High Speed\n", usb_index);
} else {
    /* Device is operating at Full Speed or lower */
    ca_printf("USB device %u is running at Full Speed\n", usb_index);
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_get_speed in my application?
A: You should call this function during the USB enumeration process or when diagnosing connection issues to verify if the device has successfully negotiated High-Speed (HS) or Full-Speed (FS) mode. It is typically called after the USB stack has been initialized and the device has been connected to a host, often paired with ca_usb_hs_dev_init.

Code example conf:1.00 **Q:** Provide a minimal example of how to check the USB speed using caOS types.
A: u32 usb_index = 0; ca_usb_speed_t speed = ca_usb_hs_dev_get_speed(usb_index); if (speed == CA_USB_SPEED_HS) { /* Handle High-Speed logic */ }

Parameters conf:1.00 **Q:** What does the usb_num parameter represent and what are the valid values?
A: The usb_num parameter is the index of the USB peripheral to query. Valid values are typically 0 or 1, depending on the specific STM32 hardware configuration. Passing an out-of-bounds index can lead to undefined behavior or return a default speed value.

Return conf:1.00 **Q:** What do the return values of ca_usb_hs_dev_get_speed indicate and what happens on failure?
A: The function returns a ca_usb_speed_t enum value, such as CA_USB_SPEED_HS or CA_USB_SPEED_FS. If an invalid index is provided, the function may return a default value like CA_USB_SPEED_FS, depending on the specific hardware implementation.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_get_speed differ between the H7xx family and other families like F4xx?
A: In the H7xx family, the function performs a bounds check (usb_num < 2U) and returns the speed from a global state array (g_usb[usb_num].speed), defaulting to CA_USB_SPEED_FS. In contrast, families like F1xx, F4xx, F7xx, H5xx, and U5xx currently implement the function as a stub that ignores the input index and always returns CA_USB_SPEED_HS.

`ca_usb_hs_dev_gpio_init`

Header: `caos/drivers/inc/ca_glue_hw.h:49`
GUARD: `EN_CA_GLUE_HW`

```c
extern void ca_usb_hs_dev_gpio_init(u32 usb_num)
```

Configures the physical GPIO pins required for the High-Speed USB peripheral interface.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral to configure. Typically 0 for the primary HS controller. Invalid values may result in no pins being configured or undefined behavior depending on the specific MCU implementation.

Ritorna:
void

Note:

- This function is a low-level hardware abstraction layer (HAL) call. It is non-blocking and executes synchronously to set up the GPIO registers (mode, speed, pull-up/down). It is not thread-safe and must be called during the system initialization phase before the USB peripheral is enabled. It is not intended to be called from an ISR. A common mistake is calling this function after the USB peripheral has already been initialized or while it is active, which can cause electrical contention or hardware faults.

Uso:

- This function is used exclusively during the board bring-up or peripheral initialization sequence. It is typically paired with ca_usb_hs_dev_clock_init to prepare the hardware environment before calling ca_usb_hs_dev_init. In a standard application, you would call this once at startup to map the physical pins to the USB controller's alternate function mode.

Esempio:

```c
/* Initialize the USB HS hardware pins before starting the USB stack */
void system_usb_setup(void) {
    /* Configure GPIOs for USB HS controller 0 */
    ca_usb_hs_dev_gpio_init(0U);

    /* Initialize the clock for the USB HS peripheral */
    ca_usb_hs_dev_clock_init(0U);

    /* Proceed to initialize the USB device stack */
    /* ca_usb_hs_dev_init(0U); // Function to initialize the USB controller */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_gpio_init in my application startup sequence?
A: This function should be called during the system initialization phase, specifically during board bring-up. It must be executed before the USB peripheral is enabled, typically paired with ca_usb_hs_dev_clock_init, and before calling ca_usb_hs_dev_init.

Code example conf:0.90 **Q:** Provide a minimal C example for initializing the primary USB HS controller.
A: u32 usb_index = 0U; ca_usb_hs_dev_clock_init(usb_index); ca_usb_hs_dev_gpio_init(usb_ind
ca_usb_hs_dev_init(usb_index);

Parameters conf:1.00 **Q:** What does the usb_num parameter represent and what are the consequences of passing an invalid value?
A: The usb_num parameter is the index of the USB peripheral to configure, where 0 is typically used for the primary HS controller. Passing invalid values may result in no pins being configured or undefined behavior depending on the specific MCU implementation.

Error/Edge case conf:1.00 **Q:** What is a common mistake when calling ca_usb_hs_dev_gpio_init?
A: A common mistake is calling this function after the USB peripheral has already been initialized or while it is active. This can cause electrical contention or hardware faults.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_gpio_init thread-safe or ISR-safe?
A: The function is not thread-safe and is not intended to be called from an ISR. It is a non-blocking, synchronous function that configures GPIO registers.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_gpio_init differ across MCU families?
A: For the H7xx family, the function explicitly configures specific GPIO ports (A, B, C, H, I) with alternate functions and high-speed settings. In contrast, for the F1xx, F4xx, F7xx, H5xx, and U5xx families, the function is currently implemented as a stub that performs no operations, as indicated by the (void)n cast.

`ca_usb_hs_dev_init`

Header: `caos/drivers/inc/ca_glue_hw.h:50`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_usb_hs_dev_init(u32 usb_num, const ca_usb_cb_t *cb)
```

Initializes the High-Speed USB peripheral hardware and registers the callback structure for device operations.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (0 or 1). Values >= 2 are invalid and will cause the function to return false.
`cb`	`const ca_usb_cb_t *`	Pointer to a structure containing callback functions for USB events. Must not be NULL.

Ritorna:
Returns true if initialization was successful, false if parameters were invalid or if the hardware failed to reset/initialize within the timeout period.

Note:

- This function performs low-level hardware configuration, including clock gating, DMA setup, and FIFO allocation. It is not thread-safe and must be called during the system initialization phase before any USB communication begins. It is not intended to be called from an ISR. A common mistake is calling this function before the necessary GPIO and clock configuration functions have been executed, which will lead to a timeout during the hardware reset phase.

Uso:

- This function is the first step in the USB device initialization sequence. It is typically followed by ca_usb_dev_mng_add to register specific USB interfaces (like CDC or HID) and finally ca_usb_dev_mng_start to enable the pull-up resistor and allow the host to enumerate the device. It should only be called once per peripheral instance during the application startup.

Esempio:

```
/* Define the callback structure for USB events */
const ca_usb_cb_t my_usb_callbacks = { /* ... callback function pointers ... */
    };

void usb_setup_task(void) {
```

```
    u32 usb_instance = 0;

    /* Perform hardware-specific clock and GPIO setup before initializing the
    driver */
    ca_usb_hs_dev_clock_init(usb_instance);
    ca_usb_hs_dev_gpio_init(usb_instance);

    /* Initialize the USB HS peripheral */
    if (ca_usb_hs_dev_init(usb_instance, &my_usb_callbacks)) {
        /* Proceed to add device classes and start the USB manager */
        /* ca_usb_dev_mng_add(...) */
        /* ca_usb_dev_mng_start(...) */
    } else {
        /* Handle initialization failure */
        ca_printf("USB HS Init Failed!\n");
    }
}
```

Q&A — fine-tuning review *7/7 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** At what point in the application lifecycle should I call ca_usb_hs_dev_init?
A: It must be called during the system initialization phase, before any USB communication begins. It is the first step in the USB device initialization sequence, typically followed by ca_usb_dev_mng_add and ca_usb_dev_mng_start.

Code example conf:0.90 **Q:** Provide a minimal C example for initializing the USB peripheral.
A: ca_usb_cb_t my_cbs = {0}; u32 usb_idx = 0U; if (ca_usb_hs_dev_init(usb_idx, &my_cbs)) { /* Success */ }

Parameters conf:1.00 **Q:** What are the constraints for the usb_num and cb parameters?
A: usb_num must be 0 or 1; values >= 2 are invalid. The cb parameter is a pointer to a ca_usb_cb_t structure and must not be NULL.

Return conf:1.00 **Q:** What does a false return value from ca_usb_hs_dev_init indicate?
A: It indicates that the initialization failed. This occurs if the input parameters are invalid (e.g., usb_num >= 2 or NULL callback) or if the hardware failed to reset/initialize within the specified timeout period.

Error/Edge case conf:1.00 **Q:** What is a common mistake that leads to a timeout during the hardware reset phase?
A: A common mistake is calling ca_usb_hs_dev_init before the necessary GPIO and clock configuration functions have been executed.

Behavior conf:1.00 **Q:** Is ca_usb_hs_dev_init thread-safe or ISR-safe?
A: The function is not thread-safe and is not intended to be called from an ISR. It performs low-level hardware configuration including clock gating, DMA setup, and FIFO allocation.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_init differ across STM32 families?
A: For the H7xx family, the function performs complex DWC2 peripheral register configuration (e.g., GAHBCFG, GUSBCFG, GRSTCTL). In contrast, the provided implementations for f1xx, f4xx, f7xx, h5xx, and u5xx are stubs that return false and perform no operations.

`ca_usb_hs_dev_isr`

Header: `caos/drivers/inc/ca_glue_hw.h:56`
GUARD: `EN_CA_GLUE_HW`

```
extern void ca_usb_hs_dev_isr(u32 usb_num)
```

Interrupt Service Routine (ISR) for handling High-Speed USB device events.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 or 1 for STM32H7). Must be a valid index supported by the hardware.

Ritorna:
void

Note:

- This function is an Interrupt Service Routine (ISR) and must be called directly from the hardware interrupt vector table for the USB peripheral. It is not thread-safe and must never be called from a standard task or thread context. Because it runs in an interrupt context, it must execute as quickly as possible; avoid performing heavy processing or blocking operations inside this function. The function handles low-level USB events like bus resets, enumeration, and endpoint interrupts by clearing hardware flags and triggering internal state machine updates.

Uso:

- This function is the backbone of the USB device stack. It is typically registered in the startup code or the NVIC configuration to be triggered automatically by the hardware whenever a USB event occurs. It works in conjunction with the USB initialization sequence (e.g., ca_usb_hs_dev_init) and the endpoint management functions. You do not call this manually; the hardware triggers it, and it in turn calls internal handlers to manage the USB protocol state machine.

Esempio:

```c
/* Example of how the USB interrupt is linked to the hardware vector */
void OTG_HS_IRQHandler(void) {
    /* Call the caOS USB ISR handler for the first USB peripheral */
    ca_usb_hs_dev_isr(0);
}

/* Typical initialization sequence in a task */
void usb_task(void *p) {
    /* Initialize the USB hardware peripheral */
    /* ca_usb_hs_dev_init(0); */

    while(1) {
        /* Wait for USB events or process data */
        ca_os_delay_ms(100);
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I manually call ca_usb_hs_dev_isr in my application code?
A: You should never call ca_usb_hs_dev_isr manually. It is an Interrupt Service Routine (ISR) designed to be triggered automatically by the hardware. It must be registered in the startup code or NVIC configuration to handle USB events like resets and enumeration directly from the hardware interrupt vector table.

Code example conf:0.90 **Q:** How do I register the ISR for a USB peripheral in caOS?
A: The function is typically registered in the startup code or NVIC configuration. While the specific NVIC registration code depends on the architecture, the ISR signature is: void ca_usb_hs_dev_isr(u32 usb_num);. For example, to handle USB peripheral 0, the hardware vector table would point to this function.

Parameters conf:1.00 **Q:** What does the u32 usb_num parameter represent?
A: The usb_num parameter is the index of the USB peripheral, such as 0 or 1 for STM32H7 devices. It must be a valid index supported by the specific hardware implementation to ensure the function accesses the correct USB_OTG_GlobalTypeDef registers.

Error/Edge case conf:1.00 **Q:** Can I perform heavy data processing or blocking operations inside ca_usb_hs_dev_isr?
A: No. Because this function runs in an interrupt context, it must execute as quickly as possible. Performing heavy processing or blocking operations is prohibited as it will interfere with the USB protocol state machine and system stability.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_isr differ between the STM32H7 and other families like F1xx or F4xx?
A: In the H7xx family, the function actively manages the DWC2 peripheral by reading GINTSTS and GINTMSK registers to handle specific events like USBRST, ENUMDNE, and endpoint interrupts. In contrast, the implementations for F1xx, F4xx, F7xx, H5xx, and U5xx provided in the documentation are currently empty stubs that perform no operations.

`ca_usb_hs_dev_set_address`

Header: `caos/drivers/inc/ca_glue_hw.h:54`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_usb_hs_dev_set_address(u32 usb_num, u8 addr)
```

Sets the USB device address in the hardware register during the enumeration process.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB peripheral (e.g., 0 for USB_OTG_HS). Must be a valid hardware index.
`addr`	`u8`	The 7-bit address assigned by the USB host during the SET_ADDRESS request. Valid range is 0 to 127.

Ritorna:
void

Note:

- This function is a low-level hardware abstraction that directly modifies the USB peripheral's device configuration register. It is not thread-safe and is typically called from the USB interrupt service routine (ISR) when the host sends a SET_ADDRESS request. It is non-blocking and executes immediately. A common mistake is calling this function before the USB peripheral has been properly initialized or while the device is in a state where address changes are prohibited by the USB specification.

Uso:

- This function is used exclusively during the USB enumeration phase. It is typically called after the device receives a SETUP packet containing the SET_ADDRESS request from the host. It is usually paired with other low-level USB functions that handle endpoint management and status reporting. Once the address is set, the hardware will respond to the new address for subsequent transactions.

Esempio:

```
/* Example: Handling a USB SET_ADDRESS request in the USB ISR */
void usb_handle_setup_packet(u32 usb_num, u8 new_addr) {
    /* The host has requested a new address.
       We must update the hardware register to match the assigned address. */
    ca_usb_hs_dev_set_address(usb_num, new_addr);

    /* After setting the address, we typically send a zero-length status packet
       to acknowledge the request to the host. */
    /* ca_usb_hs_dev_ep_write(usb_num, 0, NULL, 0); // Send status stage */
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_usb_hs_dev_set_address in my USB stack implementation?
A: This function should be called exclusively during the USB enumeration phase, specifically after the device receives a SETUP packet containing the SET_ADDRESS request from the host. It is typically invoked from within the USB interrupt service routine (ISR).

Code example conf:1.00 **Q:** Provide a minimal example of how to use ca_usb_hs_dev_set_address.
A: void handle_set_address(u32 usb_idx, u8 new_addr) { ca_usb_hs_dev_set_address(usb_idx, new_addr); }

Parameters conf:1.00 **Q:** What are the constraints for the addr parameter in ca_usb_hs_dev_set_address?
A: The addr parameter represents the 7-bit address assigned by the USB host. The valid range is 0 to 127. Passing a value outside this range is invalid as it must conform to the USB specification for device addressing.

HW differences conf:1.00 **Q:** How does the implementation of ca_usb_hs_dev_set_address differ across STM32 families?
A: For the H7xx family, the function directly manipulates the DWC2_DEV(usb_num)->DCFG register by masking and setting the USB_OTG_DCFG_DAD bits. In contrast, for the F1xx, F4xx, F7xx, H5xx, and U5xx families, the provided implementation is a stub that performs no hardware operations, as indicated by the empty function bodies.

`ca_usb_init`

Header: `caos/drivers/inc/usb.h:86`
Source: `caos/drivers/src/usb.c:23:41`
GUARD: `EN_USB`

```
bool ca_usb_init(ca_usb_speed_t speed, u32 usb_num, const ca_usb_cb_t *
    cb)
```

Initializes the USB hardware peripheral, clocks, and GPIOs for a specific USB controller.

Parametri:

Nome	Tipo	Descrizione
speed	ca_usb_speed_t	The desired USB speed (e.g., CA_USB_SPEED_FS for Full Speed, CA_USB_SPEED_HS for High Speed). Must be supported by the hardware.
usb_num	u32	The index of the USB controller to initialize. Must be less than USB_MAX_CTRL (usually 0 or 1).
cb	const ca_usb_cb_t *	Pointer to a structure containing callback functions for USB events (e.g., reset, setup, data received). Must not be NULL.

Ritorna:
Returns true if initialization succeeded, false if the controller index is invalid or the underlying hardware driver failed to initialize.

Note:

- This function is not thread-safe and must be called during the system initialization phase before any USB communication occurs. It is not intended to be called from an ISR. The function performs hardware-level configuration (clocks and GPIOs), so it is a mandatory precondition for any other USB operations. A common mistake is calling this function multiple times for the same controller without proper deinitialization, or passing an invalid usb_num, which will immediately return false and prevent the USB peripheral from functioning.

Uso:

- This function is the entry point for the USB stack. It is typically called once at startup to prepare the hardware. After successful initialization, the developer usually calls ca_usb_connect to physically enable the D+ pull-up resistor and allow the host to enumerate the device. It is often paired with ca_usb_dev_mng_start if using the device management layer, or used directly in custom implementations where the developer manages endpoints manually.

Esempio:

```
ca_usb_cb_t cb = { .on_reset = my_reset_handler, .on_setup = my_setup_handler };

// Initialize USB controller 0 at Full Speed
if (!ca_usb_init(CA_USB_SPEED_FS, 0U, &cb)) {
    // Log error using standard output
    ca_stdout_put_n("[USB] Initialization failed!");
} else {
    // Hardware is ready, now signal the host that we are present
    ca_usb_connect(0U);
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_init and why is it important to call it before other USB functions?
A: You should call ca_usb_init before any other USB-related functions to properly configure the USB hardware controller, including setting up clocks and GPIOs. It is important because it initializes the USB controller and prepares it for operation, ensuring that the hardware is correctly set up for communication. The function must be called once before using any other USB functions in the system.

Code example conf:0.90 **Q:** Can you show a minimal C code example using ca_usb_init with caOS types?

A: ca_usb_cb_t cb = { .on_tx_done = NULL, .on_rx_done = NULL }; bool success = ca_usb_init(0, &cb);

Parameters conf:0.90 **Q:** What does the usb_num parameter in ca_usb_init represent, and what are valid values for it?

A: The usb_num parameter specifies which USB controller to initialize (e.g., 0 for USB0, 1 for USB1). Valid values depend on the specific STM32 device being used, and invalid values may cause hardware errors or undefined behavior. The parameter must correspond to a supported USB controller on the target microcontroller.

Return conf:0.95 **Q:** What does ca_usb_init return, and what causes it to return false?

A: ca_usb_init returns true if initialization is successful, and false if it fails. Failures can be caused by an invalid usb_num, a NULL callback pointer (cb), or hardware errors such as incorrect clock or GPIO configuration. The function may also fail if the USB controller is not enabled or supported by the device.

`ca_usb_isr`

Header: `caos/drivers/inc/usb.h:105`
Source: `caos/drivers/src/usb.c:73:77`
GUARD: `EN_USB`

```
void ca_usb_isr(u32 usb_num)
```

Dispatches USB hardware interrupts to the registered driver callback for a specific USB controller.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller (e.g., 0 for USB_OTG_FS). Must be less than USB_MAX_CTRL.

Ritorna:
void

Note:

- This function is designed to be called directly from the STM32 hardware interrupt vector (ISR). It is non-blocking and executes in interrupt context, meaning it must be extremely fast to avoid starving the system. It is thread-safe only if the underlying driver callback is re-entrant or protected by appropriate hardware-level locking. The most common beginner mistake is performing heavy processing or blocking operations (like waiting for a semaphore) inside the callback triggered by this ISR, which will cause system instability or missed USB events.

Uso:

- This function is the entry point for the USB peripheral's interrupt service routine. It is typically called from the STM32 startup file's vector table (e.g., OTG_FS_IRQHandler). It pairs with the driver initialization sequence where a specific callback is registered via the internal driver structure. Once the hardware triggers an interrupt, this function checks if a valid driver is registered for that controller and executes the corresponding handler to process USB packets or state changes.

Esempio:

```
/* Example of an ISR implementation in the vector table */
void OTG_FS_IRQHandler(void)
```

```c
{
    /* Dispatch the interrupt to the caOS USB driver layer */
    /* usb_num 0 corresponds to the first USB controller */
    ca_usb_isr(0);
}

/* Example of initializing the USB subsystem */
void setup_usb(void)
{
    /* Initialize the USB hardware and register callbacks */
    ca_usb_init(0);

    /* Connect the device to the bus */
    ca_usb_connect(0);

    /* Wait for connection before starting data transfer */
    if (ca_usb_cdc_wait_connected(0)) {
        /* Proceed with data transmission */
        ca_usb_cdc_write(0, "Hello USB", 9);
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should ca_usb_isr() be called, and why is it important for USB interrupt handling?
A: ca_usb_isr() should be called from an Interrupt Service Routine (ISR) to handle USB interrupts. It is important because it processes USB events by calling the corresponding hardware interrupt handler, ensuring proper communication with USB devices. It must only be invoked from ISR context and not from RTOS tasks or non-interrupt code.

Code example conf:0.90 **Q:** Can you provide a minimal C example showing how to use ca_usb_isr() with caOS types?
A: void USB0_IRQHandler(void) { ca_usb_isr(0); }
void USB1_IRQHandler(void) { ca_usb_isr(1); }

Parameters conf:0.90 **Q:** What does the usb_num parameter in ca_usb_isr() represent, and what are the valid values?
A: The usb_num parameter specifies which USB controller to handle interrupts for. Valid values are 0 or 1, corresponding to USB0 and USB1 respectively. Using any other value (e.g., 2 or more) may lead to crashes or undefined behavior because ca_usb_hw_isr might access invalid hardware registers.

`ca_usb_ncm_is_up`

Header: `caos/usb/inc/usb_ncm.h:88`
Source: `caos/usb/src/usb_ncm.c:433:436`
GUARD: `EN_USB_NCM`

```c
bool ca_usb_ncm_is_up(void)
```

Returns the current connection status of the USB NCM (Network Control Model) interface.

Ritorna:
Returns true if the USB NCM link is established and ready for data transfer, false otherwise.

Note:

- This function is non-blocking and thread-safe, as it simply reads a static internal state variable maintained by the USB stack. It is safe to call from both tasks and ISRs. The most

common mistake is assuming that a 'true' return value guarantees that the host has already assigned an IP address or that the network stack is fully configured; it only indicates that the USB physical and logical link (NCM) is active. Ensure the USB subsystem has been initialized via the appropriate stack startup functions before relying on this status.

Uso:

- This function is typically used in monitoring tasks or network management loops to detect when the USB cable is plugged in or the host has initialized the NCM driver. It is often paired with ca_os_sleep to poll the link status periodically without starving other tasks of CPU time. Developers use it to gate network-dependent operations, such as starting DHCP or sending data, ensuring that the application does not attempt to transmit frames over a disconnected USB interface.

Esempio:

```c
/* Monitor USB NCM link status and report changes */
void usb_monitor_task(void *arg) {
    bool prev_up = false;
    while (1) {
        bool current_up = ca_usb_ncm_is_up();

        if (current_up != prev_up) {
            ca_stdout_printf_n("[USB] Link status changed to: %s", current_up ? "UP" : "DOWN");
            prev_up = current_up;
        }

        /* Wait 500ms before checking again to save CPU cycles */
        ca_os_sleep(500U);
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ncm_is_up() in my embedded application?
A: You should call ca_usb_ncm_is_up() to check the current state of the USB NCM connection without blocking the calling thread. It is useful for periodic status checks or conditional logic in your application where you need to know if the USB network connection is active. It is not meant to be called from an ISR since it's not designed for interrupt context.

Code example conf:0.90 **Q:** Can you show a minimal C code example using ca_usb_ncm_is_up() with caOS types?
A: bool is_up = ca_usb_ncm_is_up(); if (is_up) { // USB NCM is active } else { // USB NCM is not active }

Return conf:0.95 **Q:** What do the return values of ca_usb_ncm_is_up() indicate and what could cause it to fail?
A: The function returns true if the USB NCM connection is active (UP) and false if it is not active (DOWN). It cannot fail because it only reads a global variable and does not perform any operations that could result in an error. There are no preconditions or failure modes associated with this function.

`ca_usb_ncm_send_frame`

Header: `caos/usb/inc/usb_ncm.h:85`
Source: `caos/usb/src/usb_ncm.c:393:431`
GUARD: `EN_USB_NCM`

```
bool ca_usb_ncm_send_frame(const u8 *eth, u16 len)
```

Encapsulates an Ethernet frame into a USB NCM NTB (Network Transfer Block) and sends it over the USB bulk endpoint.

Parametri:

Nome	Tipo	Descrizione
`eth`	`const u8 *`	Pointer to the Ethernet frame buffer. Must not be NULL.
`len`	`u16`	Length of the Ethernet frame in bytes. Must be greater than 0 and less than or equal to USB_NCM_MAX_FRAME.

Ritorna:
Returns true if the frame was successfully encapsulated and queued for transmission, false otherwise (e.g., USB not initialized, invalid parameters, or frame too large).

Note:

- This function is not thread-safe and should not be called from an ISR. It performs memory operations and interacts with the USB stack, which requires a stable, initialized USB state. The function is blocking in the sense that it performs the encapsulation and triggers the USB transfer, but it does not wait for the hardware to finish the physical transmission. A common mistake is passing a buffer that is not properly aligned or is larger than the defined USB_NCM_MAX_FRAME, which will cause the function to return false immediately.

Uso:

- This function is typically used in the network interface layer to transmit outgoing Ethernet packets over a USB NCM connection. It is usually called after a network buffer has been prepared by the stack. In a typical sequence, you would receive a buffer from the network stack, call this function to send it, and if it returns true, you must free the network buffer using ca_net_buf_free to prevent memory leaks. It is the primary bridge between the generic Ethernet frame format and the USB-specific NCM protocol encapsulation.

Esempio:

```
/* Example: Sending a network buffer over NCM */
#include "caos.h"

void send_packet_example(u16 buf_idx) {
    /* Retrieve the network buffer pointer */
    ca_net_buf_t *b = ca_net_buf_ptr(buf_idx);

    if (b != NULL) {
        /* Attempt to send the frame via NCM */
        bool success = ca_usb_ncm_send_frame(b->data + b->data_off, b->data_len)
    ;

        if (success) {
            /* If sent successfully, release the buffer back to the pool */
            ca_net_buf_free(buf_idx);
        } else {
            /* Handle error: log or drop the packet */
            ca_printf("Failed to send NCM frame\n");
        }
    }
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_ncm_send_frame in a caOS application?
A: You should call ca_usb_ncm_send_frame when you need to transmit an Ethernet frame over USB-NCM interface. It is typically used in network applications where data needs to be sent from the microcontroller to a host PC via USB. The function encapsulates the Ethernet frame into a USB NTB and sends it via bulk-in endpoint.

Code example conf:0.90 **Q:** Can you provide a minimal C example showing how to use ca_usb_ncm_send_fram
A: u8 eth_frame[64] = {0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x08}; bool success = ca_usb_ncm_send_frame(eth_frame, 64); if (!success) { // Handle error }

Parameters conf:0.95 **Q:** What are the valid ranges for the eth buffer pointer and len parameter in ca_usb_ncm_send_frame?
A: The eth parameter must point to a valid, non-NULL buffer containing the Ethernet frame. The len parameter must be greater than 0 and less than or equal to USB_NCM_MAX_FRAME (typically 1514 bytes). Values outside this range will cause the function to return false immediately.

Return conf:0.95 **Q:** What does it mean when ca_usb_ncm_send_frame returns false?
A: A return value of false indicates that the frame was not sent successfully. This can happen due to invalid parameters (like NULL buffer or len out of range), an inactive NCM interface (s_up is false), NTB size exceeding limits, or errors during USB transfer.

Error/Edge case conf:0.85 **Q:** What are common mistakes when using ca_usb_ncm_send_frame?
A: Common mistakes include calling the function with a NULL eth buffer pointer, passing a len parameter that is zero or exceeds USB_NCM_MAX_FRAME, calling the function from an ISR context (not thread-safe), and not ensuring the NCM interface is active (s_up must be true). Also, the caller must free the input buffer after successful transmission.

Behavior conf:0.90 **Q:** Is ca_usb_ncm_send_frame blocking or non-blocking, and is it safe to call from an ISR?
A: The function is blocking only if ca_usb_ep_write is blocking (which depends on the underlying USB driver). It is not ISR-safe and must be called from a task context. It is also not thread-safe by itself and requires protection in a multitasking environment.

`ca_usb_set_address`

Header: `caos/drivers/inc/usb.h:99`
Source: `caos/drivers/src/usb.c:61:65`
GUARD: `EN_USB`

```
1 void ca_usb_set_address(u32 usb_num, u8 addr)
```

Updates the USB device address assigned by the host during the enumeration process.

Parametri:

Nome	Tipo	Descrizione
`usb_num`	`u32`	The index of the USB controller instance. Must be less than USB_MAX_CTRL.
`addr`	`u8`	The 7-bit address assigned by the USB host. Values above 127 are invalid.

Ritorna:
void. This function does not return a status code.

Note:

- This function is a low-level driver call used specifically during the USB enumeration phase. It is not thread-safe and must be called only when the USB controller is initialized and

active. It is typically called in response to a SET_ADDRESS request from the host. A common mistake is calling this function before the host has actually requested the address change or using an invalid address range, which will cause the device to drop off the USB bus.

Uso:

- This function is used during the USB device enumeration sequence. It is typically paired with ca_usb_ep_write to send a zero-length status packet back to the host after the address has been updated. It is called after the device receives a setup packet containing the USB_REQ_SET_ADDRESS request, ensuring the hardware is ready to respond to the new address for subsequent transactions.

Esempio:

```
/* Example: Handling a SET_ADDRESS request from the USB host */
void handle_usb_setup_request(u32 usb_num, u8 request, u16 value) {
    if (request == 0x05U) { /* USB_REQ_SET_ADDRESS */
        u8 new_addr = (u8)(value & 0x7FU);

        /* Apply the new address to the USB hardware */
        ca_usb_set_address(usb_num, new_addr);

        /* Send a zero-length status packet to acknowledge the request */
        /* ca_usb_ep_write(usb_num, 0x80U, NULL, 0U); */
    }
}
```

Q&A — fine-tuning review *3/3 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_usb_set_address and why is it important in USB communication?
A: You should call ca_usb_set_address after receiving a SET_ADDRESS request on endpoint 0 (EP0) during the USB configuration process. This function is important because it assigns a unique address to the USB device, which is required for subsequent communication with the host. It must be called in a non-ISR context and is typically used in the USB driver's configuration handling logic.

Code example conf:0.90 **Q:** Can you provide a minimal C code example showing how to use ca_usb_set_address with caOS types?
A: u32 usb_num = 0; u8 addr = 5; ca_usb_set_address(usb_num, addr);

Parameters conf:0.90 **Q:** What are the valid ranges for the parameters in ca_usb_set_address and what happens if invalid values are passed?
A: The usb_num parameter must be a valid USB interface number, typically 0 or 1 depending on the chip's capabilities. The addr parameter must be between 1 and 127, as 0 is reserved for the default address. Passing invalid values such as 0 or values greater than 127 may lead to unpredictable behavior or hardware errors, as the function does not validate these inputs.

`ca_valid_pointer`

Header: `caos/inc/utils.h:77`
Source: `caos/src/utils.c:171:180`
GUARD: `EN_UTILS`

```
bool ca_valid_pointer(const void *ptr)
```

Checks if a memory address falls within the valid, defined memory regions of the system.

Parametri:

Nome	Tipo	Descrizione
`ptr`	`const void *`	The memory address to validate. Can be any pointer; NULL is treated as invalid.

Ritorna:
Returns true if the address is within a valid memory range (e.g., RAM, Flash), false otherwise.

Note:

- This function is non-blocking and thread-safe, making it safe to call from both standard tasks and Interrupt Service Routines (ISRs). It relies on a compile-time memory map, so it is extremely fast and does not require any dynamic initialization. The most common mistake is assuming that a 'true' return means the memory is currently allocated or safe to write to; it only confirms the address is within the hardware's valid address space. Always validate pointers before dereferencing them if they originate from external sources or untrusted buffers.

Uso:

- Use this function as a defensive programming measure when receiving pointers from external interfaces, such as communication buffers or user-provided CLI arguments. It is typically used before passing a pointer to functions like ca_memcpy or when processing data structures that might contain corrupted addresses. By checking the pointer validity first, you prevent HardFault exceptions caused by accessing invalid memory regions or peripheral registers that are not mapped in the current context.

Esempio:

```
void process_external_data(void *data_ptr, u32 size) {
    // Check if the provided pointer is within valid system memory before usage
    if (ca_valid_pointer(data_ptr)) {
        // Safe to proceed with memory operations
        // Using ca_memcpy to copy data into a local buffer
        // ca_memcpy(local_buffer, data_ptr, size);
    } else {
        // Log an error or handle the invalid pointer case
        ca_printf("Error: Received invalid memory pointer!\n");
    }
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_valid_pointer in my caOS application?
A: You should use it as a defensive programming measure when receiving pointers from external interfaces, such as communication buffers or user-provided CLI arguments. It is essential to call it before dereferencing pointers or passing them to functions like ca_memcpy to prevent HardFault exceptions caused by accessing unmapped memory regions.

Code example conf:0.90 **Q:** Provide a minimal example of how to validate a pointer before processing it.
A: void process_buffer(void *ptr) { if (ca_valid_pointer(ptr)) { u32 *data = (u32 *)ptr; /* Safe to proceed */ } }

Parameters conf:1.00 **Q:** What are the constraints for the 'ptr' parameter in ca_valid_pointer?
A: The 'ptr' parameter can be any memory address. The function treats NULL as an invalid address. It checks if the provided address falls within the system's defined memory regions, such as RAM or Flash, based on the compile-time memory map.

Return conf:1.00 **Q:** Does a 'true' return value from ca_valid_pointer guarantee that the memory is safe to write to?

A: No. A 'true' return only confirms that the address is within the hardware's valid address space (e.g., RAM or Flash). It does not guarantee that the memory is currently allocated, initialized, or safe to write to. You must still ensure the memory is logically valid for your specific operation.

---

ca_vsnprintf

Header: caos/inc/utils.h:57
Source: caos/src/utils.c:214:371
GUARD: EN_UTILS

```
int ca_vsnprintf( char *buffer, u32 size, const char *format, va_list
    args)
```

Formats a variable argument list into a provided buffer, similar to standard vsnprintf.

Parametri:

Nome	Tipo	Descrizione
buffer	char *	Pointer to the destination character array where the formatted string will be stored.
size	u32	Maximum number of bytes to write, including the null terminator. Must be greater than 0.
format	const char *	Format string containing text and specifiers (e.g., %d, %s, %x).
args	va_list	The variable argument list initialized via va_start.

Ritorna:
Returns the number of characters written (excluding the null terminator) on success. Returns -1 if the buffer is NULL, format is NULL, or size is 0.

Note:

- This function is non-blocking and thread-safe as it operates entirely on the provided stack-allocated or static buffer. It is safe to call from an ISR because it does not perform any OS-level blocking operations or resource locking. The most common beginner mistake is providing an insufficient buffer size, which will result in truncation of the output string; always ensure the buffer is large enough for the expected output. Note that this implementation does not support floating-point specifiers (like %f).

Uso:

- This function is typically used to build formatted log messages or debug strings before sending them to a peripheral or a queue. It is almost always paired with va_start and va_end macros to handle the variable argument list. In a typical workflow, you initialize a buffer, call ca_vsnprintf to populate it, and then pass that buffer to a transmission function like ca_queue_static_send or ca_stdout_printf_n.

Esempio:

```
#include <stdarg.h>

void log_message(const char *fmt, ...) {
    char buffer[64];
    va_list args;

    va_start(args, fmt);
    // Format the string into the local buffer
```

```
    int len = ca_vsnprintf(buffer, sizeof(buffer), fmt, args);
    va_end(args);

    if (len > 0) {
        // Send the formatted string to the standard output system
        ca_stdout_printf_n("%s", buffer);
    }
}
```

Q&A — fine-tuning review *6/6 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I use ca_vsnprintf in an embedded system?

A: You should use ca_vsnprintf when you need to format a string with variable arguments in an embedded environment, especially in logging, debugging, or output functions. It's ideal for generating human-readable messages from structured data, such as printing sensor values or status information to a console or log buffer.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_vsnprintf with caOS types?

A:

```
u8 buffer[64];
va_list args;
va_start(args, format);
int len = ca_vsnprintf((char*)buffer, 64, "Value: %d, String: %s", args);
va_end(args);
```

Parameters conf:0.95 **Q:** What are the valid and invalid values for the 'size' parameter in ca_vsnprintf?

A: The 'size' parameter must be greater than 0. If size is 0, the function will return -1 indicating an error. The buffer must be large enough to hold the formatted string, including the null terminator. A size of 0 is invalid and causes failure.

Return conf:0.95 **Q:** What does a return value of -1 from ca_vsnprintf indicate?

A: A return value of -1 indicates an error occurred, typically due to one or more parameters being NULL or size being zero. It signifies that the function could not process the input due to invalid arguments.

Error/Edge case conf:0.90 **Q:** What are common mistakes developers make when using ca_vsnprintf?

A: Common mistakes include passing NULL to buffer or format, not calling va_start() or va_end() correctly, or using a buffer that is too small for the formatted output. These can lead to undefined behavior or incorrect string formatting.

Behavior conf:0.90 **Q:** Is ca_vsnprintf safe to call from an ISR or thread-safe?

A: ca_vsnprintf is not safe to call from an ISR because it may use functions not allowed in ISR context or take time to execute. However, it is thread-safe if the buffer and arguments are not modified by other threads during execution.

`ca_wait_queue_dequeue`

Header: `caos/inc/sync.h:382`
Source: `caos/src/sync.c:47:67`
GUARD: `EN_SYNC`

```
ca_thread_context_t* ca_wait_queue_dequeue(ca_wait_queue_t *wq)
```

Removes and returns the first task waiting in a specific wait queue.

Parametri:

Nome	Tipo	Descrizione
`wq`	`ca_wait_queue_t*`	Pointer to the wait queue structure. Must be initialized before use.

Ritorna:
Returns a pointer to the ca_thread_context_t of the dequeued task, or NULL if the queue is empty.

Note:

- This function is not thread-safe on its own; it must be called while holding the appropriate spinlock (e.g., using ca_spinlock_lock_irq) to prevent race conditions when multiple threads access the queue. It is non-blocking and can be called from an ISR, provided the caller has already acquired the necessary synchronization primitives. A common mistake is forgetting to lock the queue before calling this function, which leads to memory corruption or inconsistent queue states. Ensure the queue is properly initialized with ca_wait_queue_init before attempting to dequeue.

Uso:

- This function is typically used in synchronization primitives or resource managers to wake up tasks that are blocked waiting for an event. It is usually paired with ca_wait_queue_enqueue to add tasks to the list and ca_scheduler_wake_waiter to notify the scheduler that the task is ready to run again. In a typical workflow, you lock the queue, dequeue the task, unlock the queue, and then call the scheduler to perform the context switch or mark the task as ready.

Esempio:

```c
/* Example: Waking up a task waiting for a resource */
ca_wait_queue_t *my_queue = &resource_wait_list;

/* Always lock the queue before modifying it */
ca_spinlock_lock_irq(&my_queue->lock);

ca_thread_context_t *task = ca_wait_queue_dequeue(my_queue);

ca_spinlock_unlock_irq(&my_queue->lock);

if (task != NULL) {
    /* Notify the scheduler that the task is no longer waiting */
    ca_scheduler_wake_waiter(task);
} else {
    /* No tasks were waiting in the queue */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use the ca_wait_queue_dequeue function in my caOS application?
A: You should use this function when implementing synchronization primitives or resource managers to wake up tasks that are blocked waiting for a specific event. It is typically used to remove a task from a wait queue so it can be marked as ready to run.

Code example conf:0.95 **Q:** Provide a minimal C example showing how to safely dequeue a task from a wait queue.
A: ca_thread_context_t *task; ca_spinlock_lock_irq(&my_lock); task = ca_wait_queue_dequeue(& ca_spinlock_unlock_irq(&my_lock); if (task != NULL) { /* proceed to wake the task */ }

Parameters conf:1.00 **Q:** What is the requirement for the wq parameter passed to ca_wait_queue_dequeue?
A: The wq parameter must be a pointer to a ca_wait_queue_t structure that has been properly initialized using ca_wait_queue_init before the dequeue operation is attempted.

Return conf:1.00 **Q:** What does the return value of ca_wait_queue_dequeue indicate?

A: It returns a pointer to the ca_thread_context_t of the task that was removed from the front of the queue. If the queue is empty, it returns NULL.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make when using ca_wait_queue_dequeu
A: A common mistake is forgetting to lock the queue using a spinlock before calling the function. This leads to race conditions, memory corruption, or inconsistent queue states when multiple threads access the queue simultaneously.

Behavior conf:1.00 **Q:** Is ca_wait_queue_dequeue thread-safe and can it be called from an ISR?
A: The function is not thread-safe on its own and requires the caller to hold a spinlock. It is non-blocking and can be called from an ISR, provided the caller has already acquired the necessary synchronization primitives.

`ca_wait_queue_enqueue`

Header: `caos/inc/sync.h:381`
Source: `caos/src/sync.c:27:42`
GUARD: `EN_SYNC`

```
void ca_wait_queue_enqueue(ca_wait_queue_t *wq, ca_thread_context_t *
    task)
```

Adds a task to a wait queue, marking it as waiting for a specific resource or event.

Parametri:

Nome	Tipo	Descrizione
`wq`	`ca_wait_queue_t *`	Pointer to the wait queue structure. Must be initialized before use.
`task`	`ca_thread_context_t *`	Pointer to the thread context of the task to be queued. Must be a valid, currently running task.

Ritorna:
void

Note:

- This function is not thread-safe on its own; it must be called while holding the appropriate spinlock associated with the wait queue to prevent race conditions. It is non-blocking, as it only performs pointer manipulation to link the task into the list. It is not intended to be called directly from an ISR, as it modifies task states that should be managed via the scheduler. The most common mistake is failing to acquire the associated spinlock before calling this function, which can lead to queue corruption or lost wake-up signals.

Uso:

- This function is used when a task needs to wait for an event (like data availability or a signal) and must be removed from the ready-to-run list. It is typically paired with ca_os_wait_prepare() or ca_os_sleep_prepare() to actually transition the task to a blocked state. The standard sequence is: lock the resource, check if the condition is met, call ca_wait_queue_enqueue() if not, prepare the wait, unlock the resource, and finally call ca_os_yield() to switch to another task.

Esempio:

```
/* Example: Waiting for a custom resource */
ca_wait_queue_t my_wq;
ca_spinlock_t my_lock;

void task_wait_for_resource(void) {
    ca_thread_context_t *ctx = ca_scheduler_get_current_context();
```

```

    ca_spinlock_lock_irq(&my_lock);

    /* Check if resource is available */
    if (resource_is_empty()) {
        /* Enqueue the current task to the wait queue */
        ca_wait_queue_enqueue(&my_wq, ctx);

        /* Prepare to block and release the lock */
        ca_os_wait_prepare();
        ca_spinlock_unlock_irq(&my_lock);

        /* Yield CPU to other tasks until signaled */
        ca_os_yield();
    } else {
        ca_spinlock_unlock_irq(&my_lock);
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wait_queue_enqueue in my caOS application?
A: You should use it when a task needs to wait for a specific event or resource, such as data availability or a signal, and needs to be removed from the ready-to-run list. It is typically used in a sequence where you lock a resource, check a condition, enqueue the task if the condition is not met, prepare the wait, unlock the resource, and finally call ca_os_yield().

Code example conf:0.90 **Q:** Provide a minimal C example showing how to use ca_wait_queue_enqueue.
A: ca_wait_queue_t my_wq; ca_thread_context_t *current_task = ca_os_get_current_task(); ca_spinlock_lock(&my_wq.lock); ca_wait_queue_enqueue(&my_wq, current_task); ca_os_wait_pr ca_spinlock_unlock(&my_wq.lock); ca_os_yield();

Parameters conf:1.00 **Q:** What are the requirements for the parameters passed to ca_wait_queue_enqueue?
A: The 'wq' parameter must be a pointer to a properly initialized ca_wait_queue_t structure. The 'task' parameter must be a pointer to a valid, currently running ca_thread_context_t.

Error/Edge case conf:1.00 **Q:** What is the most common mistake when calling ca_wait_queue_enqueue?
A: The most common mistake is failing to acquire the spinlock associated with the wait queue before calling the function. This can lead to queue corruption or lost wake-up signals.

Behavior conf:1.00 **Q:** Is ca_wait_queue_enqueue thread-safe and can I call it from an ISR?
A: The function is not thread-safe on its own; it requires the caller to hold the associated spinlock. It is non-blocking as it only performs pointer manipulation. It is not intended to be called directly from an ISR because it modifies task states that should be managed by the scheduler.

`ca_wait_queue_init`

Header: `caos/inc/sync.h:380`
Source: `caos/src/sync.c:19:22`
GUARD: `EN_SYNC`

```
void ca_wait_queue_init(ca_wait_queue_t *wq)
```

Initializes a wait queue structure by setting its head and tail pointers to NULL.

Parametri:

Nome	Tipo	Descrizione
wq	ca_wait_queue_t *	Pointer to the wait queue structure to be initialized. Must be a valid, non-NULL memory address.

Ritorna:
This function returns void and does not provide a status code.

Note:

- This function is a low-level initialization routine. It is not thread-safe on its own, so it must be called before the queue is accessed by any tasks or ISRs. It is typically used during the setup phase of a synchronization primitive (like a mutex, event group, or queue). A common mistake is to call this function on a queue that is currently being used by other tasks, which will immediately corrupt the queue state and likely cause a system crash or deadlock.

Uso:

- This function is used as part of the initialization sequence for higher-level synchronization objects. You will typically see it called inside an 'init' function (e.g., ca_event_init or ca_queue_static_init) alongside the initialization of spinlocks or other metadata. It prepares the internal list structure so that subsequent calls to enqueue or dequeue tasks can safely manage the wait list.

Esempio:

```c
/* Define a custom structure containing a wait queue */
typedef struct {
    ca_wait_queue_t wait_recv;
    ca_spinlock_t lock;
} my_sync_obj_t;

void my_sync_init(my_sync_obj_t *obj) {
    /* Initialize the wait queue before any task attempts to wait on it */
    ca_wait_queue_init(&obj->wait_recv);

    /* Initialize the spinlock to protect the queue during runtime */
    ca_spinlock_irq_init(&obj->lock);
}

/* Usage in a task context */
void task_function(void *arg) {
    my_sync_obj_t my_obj;
    my_sync_init(&my_obj);

    /* Now the queue is ready for use with ca_wait_queue_enqueue or similar */
}
```

Q&A — fine-tuning review

3/3 pairs · gemini-3.1-flash-lite

Usage conf:1.00 **Q:** When should I call ca_wait_queue_init and what happens if I call it on an active queue?
A: You should call this function during the setup phase of a synchronization primitive, before any tasks or ISRs access the queue. Calling it on a queue currently in use is a common mistake that will corrupt the queue state, likely resulting in a system crash or deadlock.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to initialize a wait queue in caOS.
A: ca_wait_queue_t my_wq;
void init_my_sync_primitive(void) { ca_wait_queue_init(&my_wq); }

Parameters conf:1.00 **Q:** What are the requirements for the wq parameter in ca_wait_queue_init?
A: The wq parameter must be a pointer to a ca_wait_queue_t structure and must be a valid, non-NULL memory address. Passing a NULL pointer is invalid.

`ca_wait_queue_is_empty`

Header: `caos/inc/sync.h:384`
Source: `caos/src/sync.c:103:105`
GUARD: `EN_SYNC`

```
bool ca_wait_queue_is_empty(ca_wait_queue_t *wq)
```

Checks if a wait queue has no tasks currently waiting for a resource.

Parametri:

Nome	Tipo	Descrizione
`wq`	`ca_wait_queue_t *`	Pointer to the wait queue structure to check. Must be a valid, initialized queue handle.

Ritorna:
Returns true if the queue is empty (no tasks waiting), false otherwise.

Note:

- This function is non-blocking and executes in constant time, making it safe to call from both thread context and Interrupt Service Routines (ISRs). It does not perform any locking internally, so it assumes the caller has already ensured the queue structure is valid and not being concurrently modified in a way that would cause a race condition. The most common mistake is calling this on an uninitialized or NULL pointer, which will lead to a hard fault. Always ensure the queue has been initialized via the appropriate setup function before checking its status.

Uso:

- This function is typically used as a guard condition before attempting to dequeue tasks or when cleaning up synchronization primitives. In a typical lifecycle, you might use it to verify if any tasks are blocked on a resource (like a mutex or semaphore) before deciding to wake them up or destroy the object. It is frequently paired with ca_wait_queue_dequeue to drain a queue of waiting tasks during system shutdown or resource deallocation sequences.

Esempio:

```
/* Example: Checking if a custom synchronization object has waiters before
    cleanup */

void cleanup_resource(ca_wait_queue_t *wq) {
    /* Check if any tasks are still waiting on this resource */
    if (!ca_wait_queue_is_empty(wq)) {
        /* If not empty, we must wake up all waiting tasks before destroying */
        while (!ca_wait_queue_is_empty(wq)) {
            /* Dequeue the task and wake it up */
            ca_thread_context_t *task = ca_wait_queue_dequeue(wq);
            if (task != NULL) {
                ca_scheduler_wake_waiter(task);
            }
        }
    }
    /* Now it is safe to proceed with resource deallocation */
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wait_queue_is_empty in my application logic?
A: You should use it as a guard condition before attempting to dequeue tasks or when cleaning up synchronization primitives. It is useful for verifying if any tasks are blocked on a resource, such as a mutex or semaphore, before deciding to wake them up or destroy the object.

Code example conf:0.90 **Q:** Provide a minimal C example showing how to check if a wait queue is empty.
A: ca_wait_queue_t *my_queue; if (ca_wait_queue_is_empty(my_queue)) { /* No tasks waiting, safe to proceed */ }

Parameters conf:1.00 **Q:** What are the requirements for the wq parameter in ca_wait_queue_is_empty?
A: The wq parameter must be a pointer to a valid, initialized ca_wait_queue_t structure. Passing an uninitialized or NULL pointer is a common mistake that will lead to a hard fault.

Return conf:1.00 **Q:** What do the return values of ca_wait_queue_is_empty indicate?
A: The function returns true if the queue is empty, meaning no tasks are currently waiting for the resource. It returns false if there are tasks waiting. Failure to provide a valid, initialized queue pointer will result in a hard fault rather than a specific return value.

`ca_wait_queue_remove`

Header: `caos/inc/sync.h:383`
Source: `caos/src/sync.c:72:101`
GUARD: `EN_SYNC`

```
1 bool ca_wait_queue_remove(ca_wait_queue_t *wq, ca_thread_context_t *task
     )
```

Removes a specific task from a wait queue, typically used when a task times out or is cancelled.

Parametri:

Nome	Tipo	Descrizione
`wq`	`ca_wait_queue_t *`	Pointer to the wait queue structure from which the task should be removed.
`task`	`ca_thread_context_t *`	Pointer to the task context to be removed. Must be a valid task currently waiting in the queue.

Ritorna:
Returns true if the task was found and successfully removed from the queue. Returns false if the task was not found in the specified queue.

Note:

- This function is not thread-safe by itself; it must be called while holding the appropriate synchronization primitive (usually a spinlock) that protects the wait queue. It is safe to call from an ISR if the spinlock is acquired using an IRQ-safe method (e.g., ca_spinlock_lock_irq). A common mistake is to attempt to remove a task from a queue without first locking the queue, which leads to race conditions where the queue pointers become corrupted. Always ensure the task is actually associated with the queue before calling this, as the function performs a linear search through the list.

Uso:

- This function is used in scenarios where a task is waiting for an event (like a notification or a message) but needs to be removed prematurely, such as when a timeout occurs or the task is terminated. It is typically paired with ca_spinlock_lock_irq to ensure atomic access to the queue structure. In the typical lifecycle, a task is added to a queue via an enqueue function, and this function is called to 'clean up' the queue if the task is no longer waiting, preventing the scheduler from attempting to wake a task that is no longer in a valid wait state.

Esempio:

```c
/* Example: Removing a task from a wait queue due to a timeout */
void handle_task_timeout(ca_wait_queue_t *wq, ca_thread_context_t *task,
    ca_spinlock_t *lock) {
    /* Acquire lock to safely modify the wait queue */
    ca_spinlock_lock_irq(lock);

    /* Attempt to remove the task from the queue */
    if (ca_wait_queue_remove(wq, task)) {
        /* Task was in the queue, now removed. Perform cleanup if necessary */
        /* e.g., task->result = TIMEOUT_ERROR; */
    }

    /* Release the lock to allow other tasks to access the queue */
    ca_spinlock_unlock_irq(lock);
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wait_queue_remove in my caOS application?
A: You should use this function when a task needs to be removed from a wait queue prematurely, such as when a task times out while waiting for an event or when a task is terminated, to prevent the scheduler from attempting to wake a task that is no longer in a valid wait state.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to safely remove a task from a wait queue.
A: ca_spinlock_lock_irq(&my_lock); bool removed = ca_wait_queue_remove(&my_wq, my_task_ptr); ca_spinlock_unlock_irq(&my_lock);

Parameters conf:1.00 **Q:** What are the requirements for the task parameter in ca_wait_queue_remove?
A: The task parameter must be a valid pointer to a ca_thread_context_t structure that is currently waiting in the specified wait queue. The function performs a linear search, so the task must be associated with the queue for the operation to succeed.

Return conf:1.00 **Q:** What do the return values of ca_wait_queue_remove indicate?
A: It returns true if the task was found and successfully removed from the queue. It returns false if the task was not found in the specified wait queue.

Error/Edge case conf:1.00 **Q:** What is a common mistake when calling ca_wait_queue_remove?
A: A common mistake is attempting to remove a task from a queue without first acquiring the appropriate synchronization primitive (like a spinlock). This leads to race conditions that can corrupt the queue pointers.

Behavior conf:1.00 **Q:** Is ca_wait_queue_remove thread-safe and can it be called from an ISR?
A: The function is not thread-safe by itself and must be called while holding the appropriate synchronization primitive. It is safe to call from an ISR provided that the spinlock is acquired using an IRQ-safe method, such as ca_spinlock_lock_irq.

---

ca_wdt_early_supported

Header: caos/drivers/inc/wdt.h:81
Source: caos/drivers/src/wdt.c:158:161
GUARD: EN_WDT

```
bool ca_wdt_early_supported(ca_wdt_type_t type)
```

Checks if the specified hardware watchdog timer supports an early warning interrupt.

Parametri:

Nome	Tipo	Descrizione
type	ca_wdt_type_t	The watchdog peripheral type (e.g., CA_WDT_TYPE_IWDG or CA_WDT_TYPE_WWDG). Must be a valid enum value defined by the hardware abstraction layer.

Ritorna:
Returns true if the hardware supports an early warning interrupt for the given type, false otherwise.

Note:

- This function is non-blocking and thread-safe, as it performs a simple read of the hardware capability configuration. It is safe to call from an ISR, though typically it is used during system initialization or task setup. The most common mistake is assuming that all watchdog types support early interrupts; failing to check this before calling ca_wdt_on_early can lead to silent failures or unexpected behavior depending on the underlying hardware implementation. Always verify support before attempting to register an early warning callback.

Uso:

- This function is used to perform a feature-check on the watchdog peripheral before attempting to configure advanced features like early warning interrupts. It is typically paired with ca_wdt_init to determine the configuration strategy: if the hardware supports early warnings, the application can register a callback using ca_wdt_on_early; if not, the application must rely on standard watchdog refreshing to prevent a system reset. This pattern ensures that the code remains portable across different STM32 microcontrollers that may have varying watchdog capabilities.

Esempio:

```
/* Check if the Independent Watchdog supports early warning before configuring
    it */
if (ca_wdt_early_supported(CA_WDT_TYPE_IWDG)) {
    /* Register a callback to be executed before the watchdog triggers a reset
    */
    ca_wdt_on_early(my_watchdog_callback, NULL);
    ca_wdt_init(1000, CA_WDT_MODE_INTERRUPT, CA_WDT_TYPE_IWDG);
} else {
    /* Fallback: standard watchdog initialization without early warning */
    ca_wdt_init(1000, CA_WDT_MODE_NORMAL, CA_WDT_TYPE_IWDG);
}

/* Periodically reload the watchdog to prevent system reset */
ca_wdt_reload();
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_early_supported and why is it necessary?
A: You should call this function during system initialization or task setup to verify if the hardware supports early warning interrupts. It is necessary because not all watchdog types support this feature; checking beforehand prevents silent failures or unexpected behavior when attempting to register a callback with ca_wdt_on_early.

Code example conf:0.90 **Q:** How do I check for early warning support in my code?
A: You can check the capability as follows: bool supported = ca_wdt_early_supported(CA_WDT_TY
if (supported) { /* proceed to register callback */ }

Parameters conf:1.00 **Q:** What does the ca_wdt_type_t parameter represent and what are valid values?
A: The parameter represents the watchdog peripheral type. Valid values are enum constants defined by the hardware abstraction layer, such as CA_WDT_TYPE_IWDG or CA_WDT_TYPE_WWDG.

Return conf:1.00 **Q:** What do the boolean return values indicate?
A: A return value of true indicates that the specific hardware watchdog peripheral supports an early warning interrupt. A return value of false indicates that the feature is not supported by that hardware, meaning the application must rely on standard watchdog refreshing instead.

`ca_wdt_enable`

Header: `caos/drivers/inc/wdt.h:40`
Source: `caos/drivers/src/wdt.c:87:108`
GUARD: `EN_WDT`

```
bool ca_wdt_enable(void)
```

Activates the hardware Watchdog Timer (WDT) to monitor system health and trigger a reset if the system hangs.

Ritorna:
Returns true if the WDT was successfully enabled or was already running. Returns false if the WDT was not initialized via ca_wdt_init or if the hardware-specific enable operation failed.

Note:

- This function is not thread-safe and should be called during the system initialization phase or from a controlled task context. It is not intended to be called from an Interrupt Service Routine (ISR). Before calling this, you must have successfully called ca_wdt_init; otherwise, the function will fail immediately. A common beginner mistake is to enable the watchdog without having a strategy to periodically call ca_wdt_reload, which will cause the system to enter an infinite reset loop.

Uso:

- The watchdog is typically enabled as the final step of the system boot sequence, once all critical peripherals and tasks are ready. It is paired with ca_wdt_init to configure the timeout and mode, and subsequently with ca_wdt_reload inside the main application loop or a dedicated monitor task. If the system fails to reach the reload point within the configured timeout, the hardware will force a system reset.

Esempio:

```
/* Initialize the WDT with a 1000ms timeout in reset mode */
if (ca_wdt_init(1000U, CA_WDT_MODE_RESET, CA_WDT_TYPE_IWDG)) {
    /* Enable the watchdog to start the countdown */
```

```
    if (ca_wdt_enable()) {
        /* System is now protected */
        while (1) {
            /* Periodically reload the watchdog to prevent reset */
            ca_wdt_reload();
            ca_os_delay_ms(500);
        }
    } else {
        /* Handle failure to enable hardware */
        ca_printf("WDT enable failed!\n");
    }
} else {
    /* Handle initialization failure */
    ca_printf("WDT init failed!\n");
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to call ca_wdt_enable in the caOS boot sequence?
A: It should be called as the final step of the system boot sequence, once all critical peripherals and tasks are ready for operation.

Code example conf:0.90 **Q:** Provide a minimal C example showing how to initialize and enable the watchdog using caOS types.
A: void system_init(void) { if (ca_wdt_init()) { bool status = ca_wdt_enable(); if (status) { /* WDT active */ } } }

Return conf:1.00 **Q:** What do the return values of ca_wdt_enable signify?
A: Returning true indicates the WDT was successfully enabled or was already running. Returning false indicates the WDT was not initialized via ca_wdt_init or the hardware-specific enable operation failed.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make when using ca_wdt_enable?
A: A common mistake is enabling the watchdog without implementing a strategy to periodically call ca_wdt_reload, which results in the system entering an infinite reset loop.

Behavior conf:1.00 **Q:** Is ca_wdt_enable thread-safe or safe to call from an ISR?
A: No, the function is not thread-safe and is not intended to be called from an Interrupt Service Routine (ISR). It should be called during system initialization or from a controlled task context.

`ca_wdt_get_timeout_ms`

Header: `caos/drivers/inc/wdt.h:42`
Source: `caos/drivers/src/wdt.c:120:134`
GUARD: `EN_WDT`

```
u32 ca_wdt_get_timeout_ms(void)
```

Retrieves the current Watchdog Timer (WDT) timeout period in milliseconds.

Ritorna:
Returns the timeout in milliseconds as a u32. Returns 0 if the WDT service has not been initialized or is in an invalid state.

Note:

- This function is thread-safe and non-blocking, making it safe to call from both tasks and Interrupt Service Routines (ISRs). It prioritizes reading the actual hardware register value

if the hardware driver supports it; otherwise, it falls back to the software-cached value. A common mistake is assuming the WDT is active before calling this; always ensure the WDT subsystem has been initialized via the appropriate init function, otherwise, you will receive a 0, which might be misinterpreted as an immediate timeout. It does not perform any hardware reset or interaction that would cause a system hang.

Uso:

- This function is typically used for system health monitoring or diagnostic logging to verify that the watchdog is configured with the expected timing parameters. It is often paired with ca_wdt_init during the system startup phase to confirm the configuration, and with ca_wdt_reload during normal operation to ensure the system remains responsive. Developers use it to dynamically adjust application logic or logging frequency based on the watchdog's strictness.

Esempio:

```c
/* Check if the watchdog is configured correctly before starting a critical task */
u32 current_timeout = ca_wdt_get_timeout_ms();

if (current_timeout == 0) {
    /* WDT not initialized, handle error or log it */
    ca_printf("Error: WDT not initialized!\n");
} else if (current_timeout < 1000) {
    /* If timeout is too short, log a warning */
    ca_printf("Warning: WDT timeout is very aggressive: %lu ms\n",
    current_timeout);
}

/* Periodically reload the watchdog to prevent system reset */
ca_wdt_reload();
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wdt_get_timeout_ms in my application?
A: You should use this function for system health monitoring or diagnostic logging to verify the watchdog is configured with the expected timing parameters. It is typically used during system startup after ca_wdt_init to confirm configuration, or during normal operation to dynamically adjust application logic or logging frequency based on the watchdog's strictness.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to check the WDT timeout.
A: u32 timeout = ca_wdt_get_timeout_ms(); if (timeout > 0) { /* Log or process the valid timeout value */ }

Return conf:1.00 **Q:** What do the return values of ca_wdt_get_timeout_ms represent?
A: The function returns the current WDT timeout period in milliseconds as a u32. A return value of 0 indicates that the WDT service has not been initialized or is currently in an invalid state.

Error/Edge case conf:1.00 **Q:** What is a common mistake when calling ca_wdt_get_timeout_ms?
A: A common mistake is assuming the WDT is active before calling the function. If the WDT subsystem has not been initialized via the appropriate init function, the call will return 0, which could be misinterpreted as an immediate timeout rather than an uninitialized state.

ca_wdt_hw_early_supported

Header: caos/drivers/inc/ca_glue_hw.h:369
GUARD: EN_CA_GLUE_HW

```
extern bool ca_wdt_hw_early_supported(ca_wdt_type_t type); /* whether
    that watchdog has an early warning interrupt here */
```

Checks if the specified watchdog hardware supports an early warning interrupt (EWI).

Parametri:

Nome	Tipo	Descrizione
type	ca_wdt_type_t	The watchdog type to query (e.g., CA_WDT_TYPE_WWDG or CA_WDT_TYPE_IWDG). Must be a valid enum value defined in the system headers.

Ritorna:
Returns true if the hardware supports an early warning interrupt for the given type, false otherwise.

Note:

- This function is non-blocking and thread-safe as it performs a simple hardware capability check. It is safe to call from an ISR because it does not interact with the OS scheduler or perform complex operations. The primary purpose is to allow drivers to validate configuration requests before attempting to initialize hardware that lacks specific features. A common mistake is assuming all watchdog types support early warnings on all STM32 families; always use this function to verify support before requesting an interrupt-based watchdog mode.

Uso:

- This function is typically used during the initialization phase of a watchdog service to validate user configuration. It is used to prevent the system from entering an invalid state where a user requests an interrupt-based watchdog on hardware that only supports a hard reset. It is usually paired with ca_wdt_init to ensure that the requested mode is compatible with the underlying MCU hardware capabilities.

Esempio:

```
/* Check if we can use an early warning interrupt for the IWDG */
ca_wdt_type_t my_wdt = CA_WDT_TYPE_IWDG;

if (ca_wdt_hw_early_supported(my_wdt)) {
    /* Hardware supports it, proceed with interrupt-based watchdog init */
    /* ca_wdt_init(timeout_ms, CA_WDT_MODE_INTERRUPT, my_wdt); */
} else {
    /* Fallback to standard reset mode or log an error */
    ca_printf("Early warning not supported on this hardware, using reset mode.\n
    ");
    /* ca_wdt_init(timeout_ms, CA_WDT_MODE_RESET, my_wdt); */
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_hw_early_supported and why is it important?
A: You should call this function during the initialization phase of your watchdog service. It is used to validate user configuration before calling ca_wdt_init, ensuring you do not attempt to enable an interrupt-based watchdog mode on hardware that only supports a hard reset.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to check for early warning support before initialization.
A: if (ca_wdt_hw_early_supported(CA_WDT_TYPE_IWDG)) { /* Proceed with interrupt-based IWDG init */ } else { /* Fallback to standard reset mode */ }

Parameters conf:1.00 **Q:** What are the valid values for the 'type' parameter in ca_wdt_hw_early_supported?
A: The 'type' parameter must be a valid enum value of type ca_wdt_type_t, such as CA_WDT_TYPE_WWDG or CA_WDT_TYPE_IWDG, as defined in the system headers.

Return conf:1.00 **Q:** What does the boolean return value indicate, and can this function fail?
A: The function returns true if the hardware supports an early warning interrupt for the specified watchdog type, and false otherwise. It is non-blocking and thread-safe, so it does not fail in the traditional sense; it simply performs a hardware capability check.

HW differences conf:1.00 **Q:** How does hardware support for early warning interrupts differ across STM32 families in caOS?
A: On F1xx, F4xx, F7xx, and H7xx families, only the WWDG supports early interrupts, while the IWDG does not. Conversely, on the H5xx and U5xx families, the function returns true for both types, as these newer MCUs support both WWDG EWI and IWDG EWCR (early wakeup).

`ca_wdt_hw_enable`

Header: `caos/drivers/inc/ca_glue_hw.h:319`
GUARD: `EN_CA_GLUE_HW`

```
1 extern bool ca_wdt_hw_enable(void); /* avvia il watchdog; dopo questa
    chiamata va ricaricato periodicamente */
```

Activates the hardware Watchdog timer (IWDG or WWDG) to monitor system health.

Ritorna:
Returns true if the hardware watchdog was successfully enabled, false otherwise. A false return usually indicates that the watchdog hardware is not initialized or the system is in an invalid state.

Note:

- This function is non-blocking and performs a direct register write to the STM32 hardware watchdog peripheral. It is not thread-safe in the sense that it should be called during the system initialization phase before the scheduler starts or within a controlled startup sequence. It is generally not intended to be called from an ISR. The most common beginner mistake is calling this function without having previously configured the watchdog peripheral, which may lead to undefined behavior or immediate system resets depending on the hardware state. Once enabled, you must ensure that the watchdog is 'kicked' (reset) periodically using the appropriate OS functions to prevent a system reset.

Uso:

- This function is used during the system boot-up sequence to arm the safety mechanism that resets the MCU if the software hangs. It is typically paired with ca_os_thread_set_watchdog to register a task for monitoring and ca_os_thread_reset_watchdog to perform the periodic 'kick'. You should call this only after the hardware clocks and watchdog peripheral have been properly initialized by the system startup code.

Esempio:

```c
/* Initialize the system and enable the watchdog */
void system_startup(void) {
    /* Assume hardware watchdog peripheral is already configured */
    if (ca_wdt_hw_enable()) {
        /* Watchdog is now active; tasks must now reset it periodically */
        ca_os_thread_set_watchdog(1000); /* Set 1000ms timeout for current task */
    } else {
        /* Handle failure: log error or enter safe state */
        ca_printf("Failed to enable WDT!\n");
    }
}

/* Inside a periodic task */
void watchdog_task(void *arg) {
    while (1) {
        /* Reset the watchdog to prevent system reset */
        ca_os_thread_reset_watchdog();
        ca_os_delay_ms(500);
    }
}
```

Q&A — fine-tuning review

5/5 pairs · qwen3-coder:latest

Usage conf:0.95 **Q:** When should I call ca_wdt_hw_enable() in my caOS application?

A: You should call ca_wdt_hw_enable() once during system initialization, typically at the start of your main function or early in the boot sequence. This function enables the hardware watchdog (IWDG or WWDG) to prevent system crashes. It must be called only once, and after this call, you must periodically reload the watchdog using ca_wdt_reload() to avoid a system reset.

Code example conf:0.90 **Q:** Can you show a minimal example of how to use ca_wdt_hw_enable() in a caOS application?

A: bool success = ca_wdt_hw_enable(); if (success) { // Watchdog is enabled, now reload it periodically ca_wdt_reload(); } else { // Handle error, watchdog type may be invalid or already enabled }

Return conf:0.95 **Q:** What does ca_wdt_hw_enable() return, and what causes it to return false?

A: The function returns true if the watchdog was successfully enabled. It returns false if the watchdog type (IWDG or WWDG) is invalid or not properly configured, or if the watchdog is already enabled. The function does not perform a reset; it only enables the watchdog hardware.

Error/Edge case conf:0.85 **Q:** What are common mistakes or edge cases when using ca_wdt_hw_enable()?

A: Common mistakes include calling ca_wdt_hw_enable() more than once, which may cause undefined behavior. It is also not thread-safe and must not be called from an ISR. Additionally, if the watchdog type is not correctly set in the global variable g_wdt_type, the function will return false. After enabling, you must ensure to periodically call ca_wdt_reload() to prevent system reset.

HW differences conf:0.80 **Q:** How does ca_wdt_hw_enable() differ between STM32F7xx and STM32H7xx MCUs?

A: The main difference is in the watchdog peripheral registers. On STM32F7xx, the function uses IWDG->KR and WWDG->CR registers, while on STM32H7xx, it uses IWDG1->KR and WWDG1->CR registers. This reflects the different watchdog peripherals used in these families, with H7xx having a dedicated IWDG1 instance.

---

ca_wdt_hw_get_timeout_ms

Header: caos/drivers/inc/ca_glue_hw.h:321
GUARD: EN_CA_GLUE_HW

```
extern u32 ca_wdt_hw_get_timeout_ms(void); /* ritorna il timeout
   effettivo in millisecondi dopo arrotondamento HW */
```

Returns the actual watchdog timeout in milliseconds after hardware-specific rounding.

Ritorna:
Returns a u32 value representing the effective timeout in milliseconds. If the hardware watchdog is not initialized or the value is not set, it may return 0.

Note:

- This function is non-blocking and thread-safe as it simply reads a global variable updated during hardware initialization. It is safe to call from an ISR, although it is rarely necessary to do so. The primary purpose is to provide the actual timing value used by the hardware peripheral, which may differ from the requested value due to clock prescalers and register limitations. A common mistake is assuming this function returns the 'requested' timeout rather than the 'actual' hardware-rounded timeout.

Uso:

- This function is typically used by the system watchdog management layer to verify the real-time constraints of the hardware. It is often called during system initialization or diagnostic routines to report the watchdog status. It is frequently paired with ca_os_thread_set_watchdog to ensure that the task's monitoring period is aligned with the actual hardware reset interval.

Esempio:

```
/* Check if the hardware watchdog is configured and report its actual timing */
u32 current_timeout = ca_wdt_hw_get_timeout_ms();

if (current_timeout > 0) {
    /* Log the actual hardware timeout value */
    ca_printf("Watchdog active with actual timeout: %lu ms\n", current_timeout);
} else {
    /* Handle case where watchdog is not initialized */
    ca_printf("Watchdog is not currently active or timeout is unknown.\n");
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_wdt_hw_get_timeout_ms() and why is it useful in a real embedded application?
A: You should call ca_wdt_hw_get_timeout_ms() when you need to verify or configure the current watchdog timeout value in your embedded application. It's useful for debugging, logging, or ensuring that the watchdog is set to an appropriate timeout value. Since it's non-blocking and can be called from any context, it's safe to use in both threads and ISRs.

Code example conf:0.90 **Q:** Can you provide a minimal C code example using ca_wdt_hw_get_timeout_ms() with caOS types?
A: u32 timeout = ca_wdt_hw_get_timeout_ms(); if (timeout == 0) { // Watchdog not initialized or invalid } else { // Use the timeout value }

Return conf:0.90 **Q:** What do the return values of ca_wdt_hw_get_timeout_ms() mean, and what causes it to return 0?

A: The function returns the current watchdog timeout in milliseconds as a u32. If it returns 0, it indicates that the watchdog is either not initialized or not available. This can happen if the watchdog hardware has not been properly configured or if the underlying hardware does not support the watchdog feature. The function does not modify the watchdog state and is not thread-safe.

HW differences conf:0.85 **Q:** Are there any differences in how ca_wdt_hw_get_timeout_ms() is implemented across different STM32 MCU families?
A: No, the implementation of ca_wdt_hw_get_timeout_ms() is consistent across all supported STM32 families (f1xx, f4xx, f7xx, h5xx, h7xx). Each family simply returns the global variable g_wdt_actual_timeout_ms, which is set during watchdog initialization. There are no differences in registers or peripherals used, as the function abstracts away hardware-specific details.

`ca_wdt_hw_init`

Header: `caos/drivers/inc/ca_glue_hw.h:330`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_wdt_hw_init(u32 timeout_ms, ca_wdt_mode_t mode,
    ca_wdt_type_t type); /* initializes the watchdog with the indicated
    timeout */
```

Initializes the hardware Watchdog timer (IWDG or WWDG) with a specific timeout and operational mode.

Parametri:

Nome	Tipo	Descrizione
`timeout_ms`	`u32`	The desired watchdog timeout period in milliseconds. Must be within the hardware-specific range supported by the MCU clock configuration.
`mode`	`ca_wdt_mode_t`	Operational mode: CA_WDT_MODE_INTERRUPT (triggers an interrupt before reset) or standard reset mode.
`type`	`ca_wdt_type_t`	The watchdog peripheral type: CA_WDT_TYPE_IWDG (Independent) or CA_WDT_TYPE_WWDG (Windowed).

Ritorna:
Returns true if the hardware was successfully configured, false if the timeout is out of range or the hardware failed to initialize.

Note:

- This function is not thread-safe and must be called during the system initialization phase before the RTOS scheduler starts. It is not intended to be called from an ISR. The function performs hardware-level register writes to configure clocks and prescalers; if the provided timeout is too short or too long for the LSI/APB clock, the calculation will fail and return false. A common mistake is calling this function after the watchdog has already been started or without ensuring the LSI clock is stable. Note that on some architectures like F1xx, the interrupt mode is not supported for IWDG.

Uso:

- This function is typically used in the board support package (BSP) or system startup sequence to ensure the system can recover from hangs. It is usually paired with ca_os_thread_set_watchdog to register a task for periodic kicking. Once initialized, the application must ensure the watchdog is serviced regularly to prevent an unwanted system reset. It should be called once during boot, as re-initialization may trigger an immediate reset or cause undefined behavior in the watchdog state machine.

Esempio:

```c
/* Initialize the Independent Watchdog for a 1000ms timeout */
#define WDT_TIMEOUT_MS 1000

void system_init(void) {
    /* Attempt to initialize the hardware watchdog */
    if (!ca_wdt_hw_init(WDT_TIMEOUT_MS, CA_WDT_MODE_INTERRUPT, CA_WDT_TYPE_IWDG)) {
        /* Log error using standard output if hardware init fails */
        ca_stdout_printf_n("Watchdog initialization failed!");
    } else {
        /* Register the current task to kick the watchdog periodically */
        ca_os_thread_set_watchdog(WDT_TIMEOUT_MS / 2);
    }
}
```

Q&A — fine-tuning review *7/7 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_wdt_hw_init() in my embedded application?
A: You should call ca_wdt_hw_init() during system initialization, typically right after the hardware is configured and before the main application logic begins. It's used to enable the watchdog timer with a specified timeout to protect against system hangs or unexpected behavior.

Code example conf:0.95 **Q:** Can you show a minimal example of how to use ca_wdt_hw_init()?
A: bool success = ca_wdt_hw_init(1000, CA_WDT_MODE_RESET, CA_WDT_TYPE_IWDG); if (!success) { /* handle error */ }

Parameters conf:0.95 **Q:** What are the valid values for the timeout_ms parameter and what happens if I pass an invalid value?
A: The timeout_ms parameter must be between 1 and 32767 milliseconds. Values less than or equal to 0 or greater than 32767 will cause the function to return false, indicating initialization failure.

Return conf:0.95 **Q:** What does it mean when ca_wdt_hw_init() returns false?
A: A return value of false indicates that the watchdog initialization failed. This can happen due to an invalid timeout_ms value, an unsupported watchdog type, or hardware-related issues such as the LSI clock not being enabled for IWDG or the APB1 clock not being enabled for WWDG.

Error/Edge case conf:0.90 **Q:** What are the most common mistakes when calling ca_wdt_hw_init()?
A: Common mistakes include passing a timeout_ms value outside the valid range (1-32767), using an unsupported watchdog type, not enabling the required clocks (LSI for IWDG or APB1 for WWDG) before calling the function, and calling the function from an ISR or in a multi-threaded context without proper synchronization.

Behavior conf:0.95 **Q:** Is ca_wdt_hw_init() safe to call from an ISR or in a multi-threaded environment?
A: No, ca_wdt_hw_init() is neither ISR-safe nor thread-safe. It modifies hardware registers and is a blocking function, making it unsuitable for use in ISRs or in contexts where multiple threads might call it concurrently without proper mutual exclusion.

HW differences conf:0.85 **Q:** How does ca_wdt_hw_init() differ between F1xx and H7xx MCUs in terms of hardware implementation?

A: On F1xx, IWDG prescaler uses 3 bits (0x07) and WWDG uses a fixed register layout without interrupt support. On H7xx, IWDG prescaler uses 4 bits (0x0F) and supports interrupt mode via WINR register, while WWDG uses RCC_APB3ENR for enabling and supports EWI bit for interrupt mode.

`ca_wdt_hw_is_enabled`

Header: `caos/drivers/inc/ca_glue_hw.h:322`
GUARD: `EN_CA_GLUE_HW`

```
extern bool ca_wdt_hw_is_enabled(void); /* ritorna true se il watchdog
      attivo e non pu  pi  essere disabilitato */
```

Checks if the hardware watchdog timer is currently active and locked.

Ritorna:
Returns true if the hardware watchdog is enabled and cannot be disabled, false otherwise.

Note:

- This function is non-blocking and thread-safe as it performs a direct register read or checks a global state variable. It is safe to call from an ISR, as it does not involve any OS primitives or blocking operations. The primary precondition is that the watchdog driver must have been initialized during system startup. A common mistake is assuming this function returns the status of the software-level watchdog management; it specifically targets the hardware peripheral state, which may differ if the software watchdog has been initialized but the hardware peripheral has not yet been triggered or configured.

Uso:

- This function is typically used by system monitoring tasks or diagnostic routines to verify if the safety watchdog is active before performing critical operations. It is often paired with other watchdog management functions to ensure the system is in a safe state. Developers use it to decide whether to proceed with a system reset or to report a fault if the watchdog is unexpectedly disabled in a production environment. It is part of the standard sequence: init -> check status -> reset/service.

Esempio:

```
/* Check if the hardware watchdog is active before proceeding with a critical
    task */
if (ca_wdt_hw_is_enabled()) {
    /* Watchdog is active, safe to proceed with critical operation */
    /* Perform critical system task here */
} else {
    /* Watchdog is not enabled, log a warning or trigger a system fault */
    ca_printf("Warning: Hardware watchdog is not enabled!\n");
}
```

Q&A — fine-tuning review *4/4 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_wdt_hw_is_enabled() in my embedded application?
A: You should call ca_wdt_hw_is_enabled() when you need to verify if the hardware watchdog is already active and cannot be disabled. This is particularly useful before attempting to reconfigure or disable the watchdog, as attempting to disable an active watchdog will fail. It's also helpful for debugging or logging purposes to confirm the watchdog state.

Code example conf:0.90 **Q:** Can you show a minimal C example using ca_wdt_hw_is_enabled() with caOS types?
A: bool check_wdt_status(void) { bool is_enabled = ca_wdt_hw_is_enabled(); if (is_enabled) { // Watchdog is active, cannot be disabled return true; } else { // Watchdog is not active return false; } }

Return conf:0.90 **Q:** What does it mean when ca_wdt_hw_is_enabled() returns true or false?
A: When ca_wdt_hw_is_enabled() returns true, it means the watchdog is active and cannot be disabled via software. When it returns false, the watchdog is either disabled or not supported on the current hardware. A return value of true typically occurs when the WWDG peripheral is enabled (e.g., WWDG->CR & WDGA bit is set) or when g_wdt_enabled is true for non-WWDG watchdog types.

HW differences conf:0.85 **Q:** How does ca_wdt_hw_is_enabled() differ between STM32F1xx and STM32H7xx families?
A: The function implementation is mostly consistent across families, but differs in register access. For STM32F1xx, STM32F4xx, and STM32F7xx, it checks WWDG->CR for WWDG type, while for STM32H7xx it checks WWDG1->CR. The non-WWDG watchdogs use a global variable g_wdt_enabled in all families. There are no significant differences in functionality or limitations between these families for this function.

`ca_wdt_hw_max_timeout_ms`

Header: `caos/drivers/inc/ca_glue_hw.h:366`
GUARD: `EN_CA_GLUE_HW`

```
1 extern u32 ca_wdt_hw_max_timeout_ms(ca_wdt_type_t type); /* longest
     timeout the family supports for that type, in ms */
```

Returns the maximum possible watchdog timeout in milliseconds for a specific hardware watchdog type.

Parametri:

Nome	Tipo	Descrizione
`type`	`ca_wdt_type_t`	The watchdog type to query, typically CA_WDT_TYPE_IWDG (Independent) or CA_WDT_TYPE_WWDG (Windowed).

Ritorna:
A 32-bit unsigned integer representing the maximum timeout in milliseconds supported by the current hardware configuration. This value is calculated based on the hardware clock frequency and the maximum prescaler settings.

Note:

- This function is non-blocking and thread-safe as it performs a simple mathematical calculation based on hardware constants. It is safe to call from an ISR because it does not interact with OS primitives or perform I/O. The primary purpose is to allow the application to validate user-provided timeout values before attempting to initialize the watchdog. A common mistake is assuming this value is constant across different STM32 families; always use this function to query the limit rather than hardcoding a value, as the underlying clock frequencies (LSI or PCLK) vary significantly between chips.

Uso:

- This function is typically used during the system initialization phase or when reconfiguring the watchdog. It is almost always paired with ca_wdt_init to perform input validation.

By checking the requested timeout against this maximum, you prevent the driver from attempting to set a watchdog period that exceeds the hardware's physical capability, which would otherwise lead to an invalid configuration or a watchdog reset loop.

Esempio:

```c
/* Check if the requested watchdog timeout is within hardware limits before
    initializing */
#include "caos.h"

void setup_watchdog(u32 requested_ms) {
    ca_wdt_type_t type = CA_WDT_TYPE_IWDG;
    u32 max_ms = ca_wdt_hw_max_timeout_ms(type);

    if (requested_ms > max_ms) {
        /* Log error: requested timeout exceeds hardware capacity */
        ca_printf("Watchdog timeout too long, capping to %lu ms\n", max_ms);
        requested_ms = max_ms;
    }

    if (!ca_wdt_init(requested_ms, CA_WDT_MODE_NORMAL, type)) {
        /* Handle initialization failure */
        ca_printf("Failed to initialize watchdog\n");
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_hw_max_timeout_ms in my application?
A: You should call this function during system initialization or when reconfiguring the watchdog. It is primarily used to validate user-provided timeout values before calling ca_wdt_init to ensure the requested duration does not exceed the hardware's physical capabilities, which prevents configuration errors or reset loops.

Code example conf:1.00 **Q:** How do I use ca_wdt_hw_max_timeout_ms to validate a timeout before initialization?
A: You can compare your desired timeout against the function's return value: u32 max_ms = ca_wdt_hw_max_timeout_ms(CA_WDT_TYPE_IWDG); if (requested_ms <= max_ms) { ca_wdt_init(CA_WDT_TYPE_IWDG, requested_ms); }

Parameters conf:1.00 **Q:** What are the valid inputs for the type parameter in ca_wdt_hw_max_timeout_ms?
A: The type parameter accepts ca_wdt_type_t values, specifically CA_WDT_TYPE_IWDG for the Independent Watchdog and CA_WDT_TYPE_WWDG for the Windowed Watchdog.

Return conf:1.00 **Q:** What does the return value of ca_wdt_hw_max_timeout_ms represent and can it fail?
A: It returns a 32-bit unsigned integer representing the maximum supported watchdog timeout in milliseconds. The function is non-blocking and thread-safe, performing a mathematical calculation based on hardware constants; it does not interact with OS primitives, so it does not 'fail' in the traditional sense.

HW differences conf:1.00 **Q:** Why is it important to use ca_wdt_hw_max_timeout_ms instead of a hardcoded constant across different STM32 families?
A: The maximum timeout depends on hardware-specific clock frequencies like LSI (for IWDG) or PCLK1 (for WWDG), which vary significantly between STM32 families. The function calculates the limit dynamically based on family-specific constants like IWDG_LSI_KHZ, PCLK1_FREQ_HZ, and prescaler registers (IWDG_PR_N, WWDG_PR_N).

ca_wdt_hw_on_early

Header: caos/drivers/inc/ca_glue_hw.h:368
GUARD: EN_CA_GLUE_HW

```
extern void ca_wdt_hw_on_early(ca_wdt_early_cb_t cb, void *arg); /*
    callback of the early warning interrupt (ISR context) */
```

Registers a callback function to be executed when the Watchdog (WDT) early warning interrupt triggers.

Parametri:

Nome	Tipo	Descrizione
cb	ca_wdt_early_cb_t	Pointer to the function to execute. Must be a valid function pointer or NULL to disable.
arg	void *	User-defined pointer passed to the callback function when it executes.

Ritorna:
void

Note:

- This function is designed to be called from a thread context to configure the hardware-level interrupt handler. The callback itself will execute in an ISR (Interrupt Service Routine) context, meaning it must be extremely fast, non-blocking, and must not use any OS primitives that could cause a context switch (like mutexes or blocking queues). A common mistake is performing heavy operations like logging or complex calculations inside the callback, which can lead to system instability or missed deadlines. The implementation uses volatile variables to ensure the callback and its argument are updated atomically relative to the hardware interrupt trigger.

Uso:

- This function is used to implement 'pre-watchdog' logic, such as saving critical system state or performing a clean shutdown before the hardware watchdog forces a hard reset. It is typically called during the system initialization phase after the watchdog has been initialized with ca_wdt_init. It pairs with the watchdog driver's internal ISR, which will invoke the registered callback when the WDT counter reaches the early warning threshold.

Esempio:

```
/* Define the callback function to be executed in ISR context */
void my_wdt_warning_handler(void *arg) {
    /* Perform minimal, non-blocking emergency actions */
    /* Example: signal a task to save state or log a critical error */
    /* Note: Do not use blocking functions here */
}

void system_setup(void) {
    /* Initialize the watchdog first */
    /* ca_wdt_init(timeout_ms); */

    /* Register the early warning callback */
    ca_wdt_on_early(my_wdt_warning_handler, NULL);

    /* Enable the watchdog */
    /* ca_wdt_enable(); */
}
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wdt_hw_on_early and what is its primary purpose?
A: You should call this function during the system initialization phase, typically after ca_wdt_init. Its purpose is to register a callback that executes when the watchdog early warning interrupt triggers, allowing you to perform critical tasks like saving system state or executing a clean shutdown before the hardware watchdog forces a hard reset.

Code example conf:1.00 **Q:** How do I register an early warning callback in caOS?
A: You pass a function pointer and an optional argument to ca_wdt_hw_on_early. Example: void my_callback(void *arg) { /* fast, non-blocking code */ } ... ca_wdt_hw_on_early(my_call NULL);

Parameters conf:1.00 **Q:** What are the constraints on the 'cb' parameter in ca_wdt_hw_on_early?
A: The 'cb' parameter must be a valid function pointer of type ca_wdt_early_cb_t or NULL. If you pass NULL, the early warning interrupt functionality is disabled. Because the callback executes in an ISR context, it must be extremely fast, non-blocking, and must not use OS primitives like mutexes or blocking queues.

HW differences conf:1.00 **Q:** Are there differences in how ca_wdt_hw_on_early is implemented across the supported STM32 families?
A: Based on the provided documentation, the implementation of ca_wdt_hw_on_early is identical across the f1xx, f4xx, f7xx, h5xx, h7xx, and u5xx families. Each implementation uses a static volatile pointer to ensure the callback and its argument are updated atomically relative to the hardware interrupt trigger.

`ca_wdt_hw_reload`

Header: `caos/drivers/inc/ca_glue_hw.h:320`
GUARD: `EN_CA_GLUE_HW`

```
1 extern void ca_wdt_hw_reload(void); /* ricarica il watchdog (kick) per
     prevenire il reset */
```

Resets the hardware watchdog timer to prevent a system reset.

Ritorna:
void

Note:

- This function is non-blocking and executes immediately by writing to the hardware registers of the watchdog peripheral. It is thread-safe because the underlying register access is atomic, meaning it can be called from multiple threads or even from an ISR without requiring additional mutexes. The primary precondition is that the watchdog must have been previously initialized by the system startup code. A common beginner mistake is to call this function too infrequently, causing the watchdog to expire and trigger a system reset, or to call it inside a tight loop that prevents other tasks from running, effectively starving the system.

Uso:

- This function is used to 'kick' or 'pet' the watchdog timer, signaling to the hardware that the software is still running correctly. It is typically called periodically within a main loop or a dedicated high-priority task to ensure the system has not hung. In a robust design, you should pair this with ca_os_thread_set_watchdog to monitor specific task health, ensuring that if a task stops responding, the watchdog is no longer reloaded and the system safely reboots.

Esempio:

```c
/* Example: Periodically reloading the watchdog in a task loop */
void watchdog_task(void *pvParameters) {
    while (1) {
        /* Perform critical system checks here */

        /* Reload the hardware watchdog to prevent reset */
        ca_wdt_hw_reload();

        /* Sleep for a duration shorter than the watchdog timeout */
        ca_os_delay_ms(500);
    }
}
```

Q&A — fine-tuning review *5/5 pairs · qwen3-coder:latest*

Usage conf:0.95 **Q:** When should I call ca_wdt_hw_reload() in my embedded application?
A: You should call ca_wdt_hw_reload() periodically to prevent a system reset caused by the watchdog timer. It is typically called in main loops or periodic tasks to 'kick' or refresh the watchdog, ensuring that the system does not reset due to inactivity. This function must only be called after the watchdog has been successfully initialized.

Code example conf:0.90 **Q:** Can you provide a minimal C example using caOS types that demonstrates how to use ca_wdt_hw_reload()?
A:

```c
u32 i;
for (i = 0; i < 1000000; i++) {
    if (i % 100000 == 0) {
        ca_wdt_hw_reload();
    }
}
```

Return conf:0.90 **Q:** What does ca_wdt_hw_reload() return, and what causes it to fail?
A: The function does not return any value. It cannot fail in a traditional sense, but it may not have any effect if the watchdog has not been initialized. The function is designed to be a no-op if the watchdog is not initialized, rather than causing an error.

Error/Edge case conf:0.85 **Q:** What are common mistakes or edge cases when using ca_wdt_hw_reload()?
A: A common mistake is calling ca_wdt_hw_reload() before initializing the watchdog, which will result in no action being taken. Another issue is calling it from an ISR when atomicity is required, as the function is not thread-safe and modifies hardware registers directly. Additionally, if the watchdog is not properly reloaded in time, the system will reset.

HW differences conf:0.80 **Q:** How does ca_wdt_hw_reload() differ between STM32 F7xx and H7xx microcontrollers?
A: The main difference lies in the watchdog peripheral registers used. For F7xx, both IWDG and WWDG registers are accessed directly from the standard IWDG and WWDG peripherals. For H7xx, IWDG1 and WWDG1 are used, indicating a different peripheral mapping or dual watchdog configuration in the H7xx family compared to F7xx.

`ca_wdt_hw_reset_cause`

Header: `caos/drivers/inc/ca_glue_hw.h:367`
GUARD: `EN_CA_GLUE_HW`

```c
extern ca_wdt_reset_t ca_wdt_hw_reset_cause(bool clear); /* watchdog
   that caused the last reset; clear = clear ALL the RCC reset flags */
```

Retrieves the hardware reset source to determine if the system was restarted by a Watchdog timer.

Parametri:

Nome	Tipo	Descrizione
`clear`	`bool`	If true, clears the internal RCC reset flags after reading them. If false, the flags remain set for subsequent reads.

Ritorna:
Returns a ca_wdt_reset_t enum value: CA_WDT_RESET_IWDG if the Independent Watchdog caused the reset, CA_WDT_RESET_WWDG if the Window Watchdog caused it, or CA_WDT_RESET_NONE if the reset was caused by another source (e.g., power-on, software reset, or pin reset).

Note:

- This function is non-blocking and thread-safe as it performs a direct read of the hardware RCC registers. It is safe to call from an ISR, although it is typically called during system initialization before the application starts. The most common beginner mistake is to call this function with 'clear = true' in multiple places; if you clear the flags early in the boot process, subsequent calls will return CA_WDT_RESET_NONE, causing you to lose the diagnostic information about why the system crashed.

Uso:

- This function is used during the early stages of system startup to perform post-mortem diagnostics. Developers typically call it once at the beginning of the application to log the reset cause to a persistent storage or a debug console. It is often paired with other system initialization functions to decide whether to enter a recovery mode or a safe state if a watchdog reset is detected.

Esempio:

```c
/* Check why the system restarted */
ca_wdt_reset_t cause = ca_wdt_reset_cause(true);

if (cause == CA_WDT_RESET_IWDG) {
    /* Log the IWDG reset event to the system console */
    ca_printf("System reset by Independent Watchdog!\n");
} else if (cause == CA_WDT_RESET_WWDG) {
    /* Log the WWDG reset event */
    ca_printf("System reset by Window Watchdog!\n");
} else {
    /* Normal power-on or other reset source */
    ca_printf("System started normally.\n");
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the best time to call ca_wdt_hw_reset_cause in my application?
A: It is typically called during the early stages of system startup, before the main application logic begins. This allows you to log the reset cause to persistent storage or a debug console to perform post-mortem diagnostics, or to decide whether to enter a recovery mode.

Code example conf:1.00 **Q:** How do I check the reset cause and store it in a variable using caOS types?
A: You should call the function once and store the result. Example: ca_wdt_reset_t cause = ca_wdt_hw_reset_cause(false); if (cause == CA_WDT_RESET_IWDG) { /* handle IWDG reset */ }

Parameters conf:1.00 **Q:** What happens if I set the 'clear' parameter to true in multiple places in my code?

A: This is a common beginner mistake. If you set 'clear' to true, the internal RCC reset flags are cleared. Subsequent calls to the function will return CA_WDT_RESET_NONE, causing you to lose the diagnostic information about the actual cause of the reset.

Return conf:1.00 **Q:** What do the different return values of ca_wdt_hw_reset_cause signify?
A: The function returns CA_WDT_RESET_IWDG if the Independent Watchdog caused the reset, CA_WDT_RESET_WWDG if the Window Watchdog caused it, and CA_WDT_RESET_N if the reset was caused by another source, such as a power-on, software reset, or pin reset.

HW differences conf:1.00 **Q:** Are there differences in how ca_wdt_hw_reset_cause interacts with hardware registers across different STM32 families?
A: Yes. Most families (f1xx, f4xx, f7xx, u5xx) read from the RCC->CSR register and use the RCC_CSR_RMVF flag to clear it. However, the h5xx family reads from the RCC->RSR register using RCC_RSR_RMVF, and the h7xx family also uses the RCC->RSR register but specifically checks for IWDG1RSTF and WWDG1RSTF flags.

`ca_wdt_init`

Header: `caos/drivers/inc/wdt.h:39`
Source: `caos/drivers/src/wdt.c:54:85`
GUARD: `EN_WDT`

```
1 bool ca_wdt_init(u32 timeout_ms, ca_wdt_mode_t mode, ca_wdt_type_t type)
```

Initializes the hardware Watchdog Timer (WDT) with a specific timeout and operational mode.

Parametri:

Nome	Tipo	Descrizione
`timeout_ms`	`u32`	Watchdog timeout duration in milliseconds. Must be between 50 and 10000 inclusive.
`mode`	`ca_wdt_mode_t`	Operational mode (e.g., CA_WDT_MODE_RESET to trigger a system reset on timeout).
`type`	`ca_wdt_type_t`	Hardware type (e.g., CA_WDT_TYPE_IWDG for Independent Watchdog).

Ritorna:
Returns true if the WDT was successfully initialized and configured. Returns false if parameters are out of range, if the WDT is already enabled, or if the hardware initialization fails.

Note:

- This function is not thread-safe and should be called during system initialization before the scheduler starts or in a controlled environment. It is not intended to be called from an ISR. The most common beginner mistake is attempting to re-initialize the WDT without checking if it is already enabled, or providing a timeout value outside the allowed 50ms-10000ms range. Once initialized, the WDT must be started using ca_wdt_enable() and periodically serviced using ca_wdt_reload() to prevent a system reset.

Uso:

- This function is the mandatory first step in the WDT lifecycle. It is typically called during the system boot sequence or within a task responsible for hardware configuration. It is always paired with ca_wdt_enable() to activate the timer. In advanced scenarios, it is used during emergency shutdown routines to force a hardware reset if the system becomes unresponsive.

Esempio:

```c
/* Initialize WDT for a 2-second timeout in reset mode */
#define WDT_TIMEOUT_MS 2000U

if (ca_wdt_init(WDT_TIMEOUT_MS, CA_WDT_MODE_RESET, CA_WDT_TYPE_IWDG)) {
    /* Successfully configured, now activate the hardware */
    if (ca_wdt_enable()) {
        /* WDT is now running; must call ca_wdt_reload() periodically */
    } else {
        /* Handle hardware enable failure */
    }
} else {
    /* Handle initialization failure (e.g., invalid timeout) */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_init in my caOS project?
A: It should be called during the system boot sequence or within a task responsible for hardware configuration, ideally before the scheduler starts.

Code example conf:0.90 **Q:** How do I initialize the watchdog timer using caOS types?
A: u32 timeout = 1000; if (ca_wdt_init(timeout, CA_WDT_MODE_RESET, CA_WDT_TYPE_IW
{ ca_wdt_enable(); }

Parameters conf:1.00 **Q:** What are the constraints for the timeout_ms parameter?
A: The timeout_ms parameter must be a u32 value between 50 and 10000 inclusive.

Return conf:1.00 **Q:** What does a false return value from ca_wdt_init indicate?
A: It indicates that the initialization failed, which occurs if parameters are out of range, the WDT is already enabled, or the hardware initialization fails.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make when using ca_wdt_init?
A: The most common mistake is attempting to re-initialize the WDT without checking if it is already enabled, or providing a timeout value outside the allowed 50ms-10000ms range.

Behavior conf:1.00 **Q:** Is ca_wdt_init thread-safe or safe to call from an ISR?
A: No, this function is not thread-safe and is not intended to be called from an ISR. It should be called in a controlled environment or during system initialization.

`ca_wdt_is_enabled`

Header: `caos/drivers/inc/wdt.h:43`
Source: `caos/drivers/src/wdt.c:136:145`
GUARD: `EN_WDT`

```c
bool ca_wdt_is_enabled(void)
```

Checks if the system watchdog timer is currently active.

Ritorna:
Returns true if the watchdog is enabled (either in hardware or software state), false otherwise.

Note:

- This function is non-blocking and thread-safe, as it performs a simple read of the internal watchdog state. It can be safely called from an ISR, as it does not involve any complex synchronization or blocking mechanisms. The function relies on the internal state initialized during the system boot sequence; if the watchdog was never initialized, it will return the default software state. A common mistake is assuming that this function resets

the watchdog timer; it only reports the status, while ca_os_thread_reset_watchdog or ca_wdt_reload must be used to prevent a system reset.

Uso:

- This function is typically used in diagnostic routines or before performing critical operations where you need to verify if the system is being monitored by the hardware watchdog. It is often paired with ca_wdt_init during the system startup phase to verify that the watchdog configuration was applied successfully. In a typical application, you might check this status before entering a long-running task to ensure the watchdog is active, or use it to decide whether to perform a manual reload.

Esempio:

```c
/* Check if the watchdog is active before starting a critical task */
if (ca_wdt_is_enabled()) {
    /* Watchdog is active, proceed with the task */
    /* Perform critical operation here */

    /* Reset the watchdog to prevent a system reset */
    ca_os_thread_reset_watchdog();
} else {
    /* Watchdog is disabled, log a warning or re-initialize */
    ca_printf("Warning: Watchdog is not enabled!\n");
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_wdt_is_enabled in my application logic?
A: You should use it during diagnostic routines or before critical operations to verify if the system is being monitored. It is also useful during startup to confirm that the configuration applied by ca_wdt_init was successful, or to decide if a manual reload is necessary before starting a long-running task.

Code example conf:0.90 **Q:** How do I check the watchdog status and perform a reload if it is active?
A: You can check the status using the boolean return value and then call the reload function:
if (ca_wdt_is_enabled()) { ca_wdt_reload(); }

Return conf:0.95 **Q:** What do the return values of ca_wdt_is_enabled indicate, and can it fail?
A: The function returns true if the watchdog is enabled (hardware or software state) and false otherwise. It does not fail in the traditional sense as it is non-blocking and thread-safe; however, if the watchdog was never initialized, it will return the default software state.

`ca_wdt_max_timeout_ms`

Header: `caos/drivers/inc/wdt.h:66`
Source: `caos/drivers/src/wdt.c:143:146`
GUARD: `EN_WDT`

```c
u32 ca_wdt_max_timeout_ms(ca_wdt_type_t type)
```

Returns the maximum supported timeout duration in milliseconds for a specific watchdog hardware type.

Parametri:

Nome	Tipo	Descrizione
type	ca_wdt_type_t	The watchdog hardware identifier (e.g., CA_WDT_TYPE_IWDG for Independent Watchdog or CA_WDT_TYPE_WWDG for Window Watchdog).

Ritorna:
A u32 value representing the maximum timeout in milliseconds. If the hardware type is invalid or unsupported, the function typically returns 0 or a default fallback value defined by the driver.

Note:

- This function is non-blocking and thread-safe, as it performs a simple read of the hardware capability configuration. It is safe to call from an ISR, although it is rarely necessary to do so. The primary purpose is to allow software to dynamically query hardware limits rather than hardcoding magic numbers. A common beginner mistake is assuming that the returned value is the current timeout; this function only returns the theoretical maximum limit, not the currently configured watchdog period.

Uso:

- This function is typically used during the initialization phase of a task or system service to validate user-provided watchdog timeout settings before calling ca_wdt_init. By comparing the requested timeout against the result of ca_wdt_max_timeout_ms, developers can implement robust error handling to reject invalid configurations that exceed hardware capabilities. It is often paired with ca_wdt_init to ensure the system remains within safe operational bounds.

Esempio:

```c
/* Example: Validating watchdog configuration before initialization */
#include "ca_os.h"

void task_watchdog_setup(void) {
    const ca_wdt_type_t wdt_type = CA_WDT_TYPE_IWDG;
    const u32 requested_ms = 5000U;

    /* Query the hardware limit for the IWDG */
    u32 max_limit = ca_wdt_max_timeout_ms(wdt_type);

    if (requested_ms > 0U && requested_ms <= max_limit) {
        /* Configuration is within hardware limits, proceed to init */
        bool success = ca_wdt_init(requested_ms, CA_WDT_MODE_RESET, wdt_type);
        if (success) {
            ca_stdout_put_n("Watchdog initialized successfully");
        }
    } else {
        /* Log error: requested timeout is out of hardware range */
        ca_stdout_put_n("Error: Requested WDT timeout exceeds hardware limit");
    }
}
```

Q&A — fine-tuning review

4/4 pairs · gemini-3.1-flash-lite

Usage conf:1.00 **Q:** When should I use ca_wdt_max_timeout_ms in my application?
A: You should use this function during the initialization phase of a task or system service. It is intended to validate user-provided watchdog timeout settings against hardware limits before calling ca_wdt_init, allowing you to reject invalid configurations dynamically instead of using hardcoded magic numbers.

Code example conf:0.90 **Q:** How do I check if a requested timeout is valid using caOS types?

A: You can compare the requested duration against the hardware limit like this: u32 max_ms = ca_wdt_max_timeout_ms(CA_WDT_TYPE_IWDG); if (requested_ms > max_ms) { /* handle error */ }.

Parameters conf:1.00 **Q:** What does the ca_wdt_type_t parameter represent?

A: The parameter represents the watchdog hardware identifier. Valid examples include CA_WDT_TYPE_IWDG for the Independent Watchdog and CA_WDT_TYPE_WWDG for the Window Watchdog.

Return conf:1.00 **Q:** What does a return value of 0 indicate from ca_wdt_max_timeout_ms?

A: A return value of 0 typically indicates that the provided hardware type is invalid or unsupported by the driver. It is important to note that this function returns the theoretical maximum limit of the hardware, not the currently configured watchdog period.

`ca_wdt_on_early`

Header: `caos/drivers/inc/wdt.h:79`
Source: `caos/drivers/src/wdt.c:153:156`
GUARD: `EN_WDT`

```
void ca_wdt_on_early(ca_wdt_early_cb_t cb, void *arg)
```

Registers a callback function to be executed just before the Watchdog timer triggers a system reset.

Parametri:

Nome	Tipo	Descrizione
`cb`	`ca_wdt_early_cb_t`	A pointer to the function to be called. Must be a valid function pointer or NULL to disable the callback.
`arg`	`void *`	A user-defined pointer passed to the callback function. Can be NULL if no context is needed.

Ritorna:
void

Note:

- This function is non-blocking and is typically called during system initialization. The callback function executes in an interrupt context (ISR), meaning it must be extremely fast, must not perform blocking operations (like waiting for semaphores or I/O), and should avoid complex memory allocations. A common beginner mistake is performing heavy logging or complex logic inside this callback, which can lead to system instability or missed reset timing. Ensure the watchdog hardware actually supports early warning interrupts before relying on this feature.

Uso:

- This function is used to perform 'last-gasp' operations, such as saving critical system state to backup registers or logging a final error code to non-volatile memory before the hardware resets. It is typically called before ca_wdt_init and ca_wdt_enable. It is often paired with ca_bkp_write to store diagnostic information that can be retrieved after the system reboots to identify why the watchdog was triggered.

Esempio:

```
/* Define the early warning callback */
void my_early_warning_cb(void *arg) {
    /* Save the error type to backup registers before reset */
```

```
    ca_bkp_write(0U, (uint32_t)arg);
}

void setup_watchdog(void) {
    /* Register the callback to run before the WDT resets the system */
    ca_wdt_on_early(my_early_warning_cb, (void *)0xDEADBEEF);

    /* Initialize WDT with interrupt mode to allow the callback to run */
    if (ca_wdt_init(1000U, CA_WDT_MODE_INTERRUPT, 0U)) {
        ca_wdt_enable();
    }
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_on_early and what is its primary purpose?
A: You should call ca_wdt_on_early during system initialization, typically before calling ca_wdt_init and ca_wdt_enable. Its purpose is to register a 'last-gasp' callback that executes just before a system reset, allowing you to perform critical operations like saving system state to backup registers or logging error codes.

Code example conf:0.90 **Q:** How do I implement a minimal callback for ca_wdt_on_early using caOS types?
A: The callback must be fast and non-blocking as it runs in an ISR. Example: void my_callback(void *arg) { u32 *err_code = (u32 *)arg; ca_bkp_write(0, *err_code); } ... ca_wdt_on_early(my_callback, &my_error_var);

Parameters conf:1.00 **Q:** What are the requirements for the 'cb' parameter in ca_wdt_on_early?
A: The 'cb' parameter must be a valid function pointer of type ca_wdt_early_cb_t, or it can be set to NULL to disable the callback. Because it executes in an interrupt context, the function must be extremely fast and avoid blocking operations or complex memory allocations.

`ca_wdt_reload`

Header: `caos/drivers/inc/wdt.h:41`
Source: `caos/drivers/src/wdt.c:110:118`
GUARD: `EN_WDT`

```
void ca_wdt_reload(void)
```

Resets the hardware watchdog timer counter to prevent a system reset.

Ritorna:
This function returns nothing (void).

Note:

- This function is non-blocking and thread-safe because the underlying hardware reload operation is atomic. It can be safely called from both standard tasks and Interrupt Service Routines (ISRs). The function will silently do nothing if the watchdog has not been previously enabled via ca_wdt_init. The most common mistake for beginners is to place this call inside a loop that can block for longer than the watchdog timeout period, which will cause the system to reset unexpectedly.

Uso:

- This function is used in the main loop or critical task cycles to signal that the system is still responsive and healthy. It is typically paired with ca_wdt_init during system startup to configure the timeout period. In a robust design, you should call this function at a

frequency significantly higher than the watchdog timeout to ensure that even if a task is slightly delayed, the system does not trigger a hardware reset.

Esempio:

```
/* Initialize the watchdog with a specific timeout before starting the loop */
ca_wdt_init();

while (1) {
    /* Perform critical system tasks */
    do_sensor_readings();

    /*
     * Reset the watchdog timer to prevent a system reset.
     * If this code is not reached within the timeout period,
     * the hardware will force a system reboot.
     */
    ca_wdt_reload();

    /* Sleep to allow other tasks to run */
    ca_os_sleep(100);
}
```

Q&A — fine-tuning review *2/2 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_wdt_reload and why is it important for system stability?
A: You should call ca_wdt_reload in your main loop or critical task cycles to signal that the system is responsive. It is important to call it at a frequency significantly higher than the watchdog timeout period to prevent unexpected system resets caused by task delays or blocking code.

Code example conf:0.90 **Q:** How do I implement a basic watchdog reload in a caOS task loop?
A: You can call the function directly within your task loop. Ensure the watchdog has been initialized first. Example: void task_loop(void) { while(1) { ca_wdt_reload(); /* perform task logic */ } }

`ca_wdt_reset_cause`

Header: `caos/drivers/inc/wdt.h:70`
Source: `caos/drivers/src/wdt.c:148:151`
GUARD: `EN_WDT`

```
ca_wdt_reset_t ca_wdt_reset_cause(bool clear)
```

Retrieves the reason for the last system reset, specifically identifying if it was triggered by the Watchdog Timer.

Parametri:

Nome	Tipo	Descrizione
`clear`	`bool`	If true, the internal hardware reset flag is cleared after reading. If false, the flag remains set for subsequent reads.

Ritorna:
Returns a ca_wdt_reset_t enumeration value representing the reset source (e.g., power-on, software reset, or watchdog timeout).

Note:

- This function is non-blocking and thread-safe, as it typically reads a hardware register directly. It is safe to call from an ISR, though it is usually called during system initialization to log the cause of a reboot. A common beginner mistake is to pass 'false' to the clear parameter during the initial boot check, which causes the system to report a watchdog reset on every subsequent boot until the flag is manually cleared.

Uso:

- This function is typically used at the very beginning of the application startup sequence, often before the main RTOS scheduler is started. It is used to determine if the system crashed due to a watchdog timeout, allowing the developer to log the event to non-volatile memory (like backup registers) for post-mortem analysis. It is often paired with ca_bkp_read and ca_bkp_write to store diagnostic information across reboots.

Esempio:

```
ca_wdt_reset_t reset_reason;

/* Check why the system rebooted */
reset_reason = ca_wdt_reset_cause(true);

/* If the reset was caused by the watchdog, log it to backup registers */
if (reset_reason == CA_WDT_RESET_TIMEOUT) {
    /* Assume bkp_mark_idx() returns a valid index for backup storage */
    ca_bkp_write(bkp_mark_idx(), 0xDEADBEEF);
}

/* Proceed with system initialization */
ca_os_run();
```

Q&A — fine-tuning review *4/4 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the best time to call ca_wdt_reset_cause in my caOS application?
A: It is typically called at the very beginning of the application startup sequence, often before the main RTOS scheduler is started. This allows the developer to determine if the system crashed due to a watchdog timeout and log the event to non-volatile memory for post-mortem analysis.

Code example conf:0.90 **Q:** Provide a minimal example of how to check the reset cause during initialization.
A: ca_wdt_reset_t cause = ca_wdt_reset_cause(true); if (cause == CA_WDT_TIMEOUT) { /* Log to backup registers */ }

Parameters conf:1.00 **Q:** What happens if I pass 'false' to the clear parameter in ca_wdt_reset_cause?
A: If you pass false, the internal hardware reset flag remains set. A common mistake is to do this during the initial boot check, which causes the system to report a watchdog reset on every subsequent boot until the flag is manually cleared.

Return conf:1.00 **Q:** What does the return value of ca_wdt_reset_cause represent?
A: It returns a ca_wdt_reset_t enumeration value representing the reset source, such as power-on, software reset, or watchdog timeout. The function is non-blocking and thread-safe as it reads the hardware register directly.

`ca_x25519`

Header: `caos/crypto/inc/x25519.h:70`
Source: `caos/crypto/src/x25519.c:435:511`
GUARD: `EN_X25519`

```
bool ca_x25519(u8 *out, const u8 *scalar, const u8 *point)
```

Performs X25519 scalar multiplication to compute a shared secret or public key.

Parametri:

Nome	Tipo	Descrizione
`out`	`u8 *`	Pointer to a 32-byte buffer where the resulting public key or shared secret will be stored.
`scalar`	`const u8 *`	Pointer to a 32-byte private scalar (clamped internally per RFC 7748).
`point`	`const u8 *`	Pointer to a 32-byte public key or base point.

Ritorna:
Returns true if the operation succeeded and the result is non-zero (valid point). Returns false if any input pointer is NULL or if the resulting point is the point at infinity (invalid result).

Note:

- This function is computationally intensive and performs a fixed-time Montgomery ladder to prevent side-channel attacks. It is NOT thread-safe if the same buffers are accessed concurrently by other tasks. It is NOT callable from an ISR due to its long execution time and stack usage. Ensure that the 'out', 'scalar', and 'point' buffers are properly aligned and allocated before calling. A common mistake is passing uninitialized or random data as the 'scalar' without ensuring it is a valid private key, or failing to check the boolean return value, which leads to using an all-zero shared secret.

Uso:

- Used primarily in cryptographic key exchange protocols (like SSH or TLS) to derive a shared secret between two parties. It is typically used in a sequence: first, generate a private scalar using ca_rng_fill, then compute the public key using ca_x25519_base, and finally compute the shared secret by calling ca_x25519 with your private scalar and the peer's public key. Always verify the return value to ensure the resulting secret is valid before proceeding with encrypted communication.

Esempio:

```
u8 my_priv[32];
u8 peer_pub[32];
u8 shared_secret[32];

/* Initialize private key with random bytes */
if (ca_rng_fill(my_priv, 32)) {
    /* Compute shared secret using peer's public key */
    if (ca_x25519(shared_secret, my_priv, peer_pub)) {
        /* Proceed to use shared_secret for encryption */
    } else {
        /* Handle error: invalid peer key or point at infinity */
    }
} else {
    /* Handle RNG failure */
}
```

Q&A — fine-tuning review *6/6 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** In what scenario should I use the ca_x25519 function?
A: It is used in cryptographic key exchange protocols like SSH or TLS to derive a shared secret. Typically, you use it after generating a private scalar with ca_rng_fill and computing your public key with ca_x25519_base, then calling ca_x25519 with your private scalar and the peer's public key.

Code example conf:1.00 **Q:** Provide a minimal C example for computing a shared secret using caOS types.

A: u8 my_secret[32]; u8 my_private[32]; u8 peer_public[32]; if (ca_x25519(my_secret, my_private, peer_public)) { /* Proceed with secure communication */ }

Parameters conf:1.00 **Q:** What are the requirements for the 'scalar' parameter in ca_x25519?

A: The 'scalar' must be a pointer to a 32-byte buffer containing the private scalar. The function internally clamps this value per RFC 7748, but you must ensure the buffer is properly allocated and initialized before calling.

Return conf:1.00 **Q:** What does a return value of false indicate for ca_x25519?

A: A return value of false indicates that the operation failed. This occurs if any input pointer is NULL or if the resulting point is the point at infinity, which is an invalid result.

Error/Edge case conf:1.00 **Q:** What is a common mistake when using ca_x25519 that leads to security issues?

A: A common mistake is failing to check the boolean return value, which can lead to using an all-zero shared secret if the operation fails. Another is passing uninitialized or random data as the scalar without ensuring it is a valid private key.

Behavior conf:1.00 **Q:** Is ca_x25519 safe to call from an interrupt service routine (ISR)?

A: No, it is not callable from an ISR due to its long execution time and stack usage. Additionally, it is not thread-safe if the same buffers are accessed concurrently by other tasks.

`ca_x25519_base`

Header: `caos/crypto/inc/x25519.h:77`
Source: `caos/crypto/src/x25519.c:513:517`
GUARD: `EN_X25519`

```
1 void ca_x25519_base(u8 *out, const u8 *scalar)
```

Computes the X25519 public key by performing scalar multiplication on the standard base point (u=9).

Parametri:

Nome	Tipo	Descrizione
`out`	`u8 *`	Pointer to a 32-byte buffer where the resulting public key will be stored. Must be allocated and valid.
`scalar`	`const u8 *`	Pointer to a 32-byte buffer containing the private scalar (secret key). Must be 32 bytes long.

Ritorna:
void. This function does not return a status code; it assumes the provided buffers are valid and of sufficient size.

Note:

- This function is a wrapper around the core X25519 algorithm, specifically hardcoded to use the RFC 7748 base point (u=9). It is computationally intensive and performs heavy mathematical operations; therefore, it should not be called from an ISR (Interrupt Service Routine) as it will block the CPU for a significant duration. It is thread-safe provided that the 'out' and 'scalar' buffers are not accessed by other tasks simultaneously. A common beginner mistake is passing uninitialized or incorrectly sized buffers, which will lead to memory corruption or invalid cryptographic keys.

Uso:

- This function is typically used during the key exchange phase of secure communication protocols (like SSH or TLS). The standard sequence involves: first, generating a random

private scalar using ca_rng_fill; second, calling ca_x25519_base to derive the corresponding public key; and finally, using the resulting public key in a handshake or key exchange process with a remote peer. It is often paired with ca_x25519 to perform the actual Diffie-Hellman shared secret calculation once the peer's public key is received.

Esempio:

```c
/* Example: Generating a local X25519 key pair for a secure session */
#define X25519_KEY_SIZE 32

void generate_keys(void) {
    u8 private_key[X25519_KEY_SIZE];
    u8 public_key[X25519_KEY_SIZE];

    /* 1. Fill private key with random bytes */
    if (ca_rng_fill(private_key, X25519_KEY_SIZE)) {
        /* 2. Derive public key from the base point (u=9) */
        ca_x25519_base(public_key, private_key);

        /* Now public_key is ready to be sent to the peer */
    } else {
        /* Handle RNG failure: log error or abort */
    }
}
```

Q&A — fine-tuning review *3/3 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I use ca_x25519_base in my caOS application?
A: You should use this function during the key exchange phase of secure communication protocols like SSH or TLS. The typical workflow is to first generate a random private scalar using ca_rng_fill, then call ca_x25519_base to derive the public key, and finally use that public key to perform a handshake with a remote peer.

Code example conf:1.00 **Q:** How do I implement a basic public key generation using ca_x25519_base?
A: You must provide two 32-byte buffers. Example: u8 private_key[32]; u8 public_key[32]; ca_rng_fill(private_key, 32); ca_x25519_base(public_key, private_key);

Parameters conf:1.00 **Q:** What are the requirements for the 'out' and 'scalar' parameters in ca_x25519_base?
A: Both 'out' and 'scalar' must be pointers to 32-byte buffers. The 'scalar' buffer must contain the private secret key, and the 'out' buffer must be allocated and valid to store the resulting public key. Passing incorrectly sized buffers will result in memory corruption or invalid cryptographic keys.

`ca_x25519_selftest`

Header: `caos/crypto/inc/x25519.h:119`
Source: `caos/crypto/src/x25519.c:571:645`
GUARD: `EN_X25519`

```c
u32 ca_x25519_selftest(void)
```

Executes a comprehensive suite of cryptographic self-tests for the X25519 algorithm to verify implementation integrity.

Ritorna:
Returns a u32 representing the total number of failed tests. A return value of 0 indicates that all tests passed successfully.

Note:

- This function is intended for diagnostic and validation purposes during system startup or maintenance. It is not thread-safe and should not be called from an ISR, as it performs significant computation and potentially uses blocking I/O for reporting. Before calling this, ensure the system clock is initialized and the cryptographic hardware/software environment is ready. A common mistake is calling this function in a production loop; it should only be executed once during the initialization phase to verify that the X25519 implementation is functioning correctly on the specific hardware platform.

Uso:

- This function is typically invoked during the system boot sequence or within a dedicated diagnostic task. It is often paired with other self-test functions like ca_ed25519_selftest or ca_sha512_selftest to ensure the entire cryptographic stack is operational. Developers use the returned value to decide whether to proceed with system initialization or to enter a safe/error state if the hardware or software implementation fails to meet the expected cryptographic standards.

Esempio:

```c
/* Example: Running X25519 self-tests during system initialization */
#include "caos.h"

void system_init_diagnostics(void) {
    u32 total_fails = 0;

    /* Initialize the X25519 test environment if required */
    ca_x25519_test_init();

    /* Execute the self-test suite */
    total_fails = ca_x25519_selftest();

    if (total_fails > 0) {
        ca_stdout_printf_n("CRITICAL: X25519 self-test failed with %u errors",
    total_fails);
        /* Enter a safe state or halt system if crypto is unreliable */
        while(1) { /* Halt */ }
    } else {
        ca_stdout_put_n("X25519 self-test passed successfully.");
    }
}
```

Q&A — fine-tuning review *5/5 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When is the appropriate time to invoke ca_x25519_selftest in a caOS project?
A: It should be invoked during the system boot sequence or within a dedicated diagnostic task. It is intended for diagnostic and validation purposes during system startup or maintenance to ensure the cryptographic stack is operational before proceeding with system initialization.

Code example conf:1.00 **Q:** Provide a minimal C example showing how to check the result of the X25519 self-test.
A: u32 result = ca_x25519_selftest(); if (result != 0) { /* Enter safe or error state */ }

Return conf:1.00 **Q:** What does the u32 return value of ca_x25519_selftest signify?
A: The return value represents the total number of failed tests. A return value of 0 indicates that all tests passed successfully, while any non-zero value indicates the number of failures encountered during the integrity verification.

Error/Edge case conf:1.00 **Q:** What is a common mistake developers make when using ca_x25519_selftest?
A: A common mistake is calling this function in a production loop. It should only be executed once during the initialization phase to verify that the X25519 implementation is functioning correctly on the specific hardware platform.

Behavior conf:1.00 **Q:** Is ca_x25519_selftest safe to call from an ISR or in a multi-threaded environment?
A: No, the function is not thread-safe and should not be called from an ISR. It performs significant computation and may use blocking I/O, so it must be executed in a context where such operations are permitted, typically during system startup.

`ca_x25519_test_init`

Header: `caos/crypto/inc/x25519.h:124`
Source: `caos/crypto/src/x25519.c:670:677`
GUARD: `EN_X25519`

```
void ca_x25519_test_init(void)
```

Registers the X25519 cryptographic test command into the Command Line Interface (CLI) system.

Ritorna:
void

Note:

- This function is a wrapper that ensures the X25519 test command is registered exactly once in the CLI system. It uses a static boolean flag to prevent duplicate registrations, which would otherwise corrupt the CLI linked list. It is not thread-safe by itself, so it must be called during the system initialization phase before the scheduler starts or within a critical section if called later. It is not intended to be called from an ISR. The most common mistake is calling this function multiple times from different tasks without ensuring the underlying CLI registration mechanism is protected, or calling it before the CLI system itself has been initialized.

Uso:

- This function is typically called during the system startup sequence, specifically within the 'ca_os_main' function or an equivalent initialization task. It is used to expose cryptographic self-tests to the user via the serial console. It is usually paired with other test initialization functions like 'ca_sha512_test_init' and 'ca_ed25519_test_init' to populate the CLI with available diagnostic commands before 'ca_os_run' is invoked.

Esempio:

```
void ca_os_main(void) {
    /* Initialize the CLI system first (assumed existing) */
    ca_cli_init();

    /* Register cryptographic test commands for CLI access */
    ca_sha512_test_init();
    ca_x25519_test_init();
    ca_ed25519_test_init();

    /* Start the OS scheduler */
    ca_os_run(true);
}
```

Q&A — fine-tuning review *2/2 pairs · gemini-3.1-flash-lite*

Usage conf:1.00 **Q:** When should I call ca_x25519_test_init and why is it important to do so during initialization?

A: You should call ca_x25519_test_init during the system startup sequence, such as within 'ca_os_main' or an initialization task, before the scheduler starts. This is critical because the function is not thread-safe and uses a static flag to prevent duplicate registrations in the CLI linked list, which would otherwise cause corruption.

Code example conf:0.95 **Q:** How do I correctly initialize the X25519 test command in my caOS startup sequence?

A: You should invoke the function during the system initialization phase before calling ca_os_run. Example: void ca_os_main(void) { ca_x25519_test_init(); ca_sha512_test_init(); ca_ed25519_test_init(); ca_os_run(); }

Chapter 115

Reference Tipi di dato caOS

Strutture, enumerazioni e callback in ordine alfabetico. Per ogni voce: definizione C, descrizione, membri, note d'uso.

ca_adc_config_t

Tipo: Struttura
File: caos/drivers/inc/adc.h:29:32

```c
typedef struct {
u8 adc_num;      /* 1, 2, 3 */
u8 sample_time;  /* 0..7 (SMPx bits, family-specific encoding) */
} ca_adc_config_t;
```

Configuration structure used to define the hardware parameters for an ADC peripheral instance in caOS.

Membri:

Nome	Tipo	Descrizione
adc_num	u8	The identifier of the ADC peripheral to be used. Valid values are 1, 2, or 3 depending on the specific STM32 chip variant. Providing an invalid number will result in a driver initialization error.
sample_time	u8	The sampling time configuration, mapped to the SMPx bits of the ADC registers. Valid range is 0 to 7. Higher values increase sampling duration, which is necessary for high-impedance signal sources to ensure accurate readings.

Note:
This structure is typically passed by value to initialization functions. It does not require dynamic memory allocation; it should be declared as a local variable or a static constant. The user is responsible for ensuring the selected adc_num is physically present on the target MCU.

Uso:
Use this struct to prepare the hardware settings before calling the ADC initialization routine. It acts as a parameter block to configure the ADC peripheral's timing and identity.

Esempio:

```c
ca_adc_config_t my_adc_cfg = { .adc_num = 1, .sample_time = 3 };

// Pass the configuration to the driver initialization function
ca_adc_init(&my_adc_cfg);
```

---

ca_adc_isr_cb_t

Tipo: Callback
File: caos/drivers/inc/adc.h:46:46

```
typedef void (*ca_adc_isr_cb_t)(u8 adc_num, u16 value)
```

A function pointer type used to define a callback function that executes when an ADC conversion completes.

Membri:

Nome	Tipo	Descrizione
adc_num	u8	The identifier of the ADC peripheral that triggered the interrupt. Must match the hardware index defined in the system configuration.
value	u16	The raw digital value captured from the ADC conversion. Range is typically 0 to 4095 for 12-bit resolution.

Note:
This callback is executed within the context of an Interrupt Service Routine (ISR). Keep the implementation extremely short and avoid blocking operations, mutexes, or heavy processing. The user is responsible for registering this callback via the driver's configuration interface.

Uso:
Use this type when you need to process ADC data asynchronously without polling. It is typically passed to the ADC driver initialization or configuration structure to handle data arrival events.

Esempio:

```
void my_adc_handler(u8 adc_num, u16 value) {
    if (adc_num == 1) {
        process_sensor_data(value);
    }
}

// Usage in configuration
ca_adc_config_t config = {
    .isr_cb = my_adc_handler
};
```

---

ca_aes_channel_t

Tipo: Struttura
File: caos/crypto/inc/aes_channel_service.h:36:46

```
typedef struct {
ca_aes_mode_t            mode;
ca_aes_keysize_t         keysize;
void                    *ks_handle;     /* keys_store pointer (
    ca_keys_store_allocate) */
ca_aes_iv_gen_cb_t       iv_gen_cb;     /* NULL     ca_rng_fill() */
ca_aes_key_ratchet_cb_t  ratchet_cb;    /* NULL     rotate disabled */
void                    *cb_user;       /* opaque for both callbacks */
ca_aes_ctx_t            *red_ctx;       /* encrypt context (heap) */
```

```
ca_aes_ctx_t             *black_ctx;     /* decrypt context (heap) */
caMutex                   mutex;
} ca_aes_channel_t;
```

A configuration and state container for managing secure AES encryption/decryption channels in caOS.

Membri:

Nome	Tipo	Descrizione
mode	ca_aes_mode_t	Defines the AES operation mode (e.g., CBC, GCM). Must match the hardware/software capability.
keysize	ca_aes_keysize_t	Specifies the AES key length (128, 192, or 256 bits). Must be compatible with the key stored in ks_handle.
ks_handle	void *	Pointer to the key store object allocated via ca_keys_store_allocate. Must not be NULL.
iv_gen_cb	ca_aes_iv_gen_cb_t	Optional callback for IV generation. If NULL, the system defaults to ca_rng_fill().
ratchet_cb	ca_aes_key_ratchet_cb_t	Optional callback for key rotation. If NULL, key ratcheting is disabled.
cb_user	void *	Opaque pointer passed to iv_gen_cb and ratchet_cb for context-specific data.
red_ctx	ca_aes_ctx_t *	Pointer to the heap-allocated encryption context. Managed by the service.
black_ctx	ca_aes_ctx_t *	Pointer to the heap-allocated decryption context. Managed by the service.
mutex	ca_mutex_t	Internal synchronization primitive to ensure thread-safe access to the channel.

Note:
The struct must be initialized to zero before use. The red_ctx and black_ctx pointers are managed by the caOS crypto service; do not manually free these pointers. The mutex is automatically initialized during channel registration. Ensure the key store handle is valid for the lifetime of the channel.

Uso:
Used to initialize and maintain a secure cryptographic channel. It is passed to ca_aes_channel_init() to prepare the contexts and mutex before performing any encryption or decryption operations.

Esempio:

```
ca_aes_channel_t my_channel = {0};
my_channel.mode = CA_AES_MODE_GCM;
my_channel.keysize = CA_AES_KEYSIZE_256;
my_channel.ks_handle = my_key_store_ptr;

if (ca_aes_channel_init(&my_channel) == CA_SUCCESS) {
    /* Channel is ready for use */
}
```

---

ca_aes_ctx_t

Tipo: Struttura
File: caos/drivers/inc/aes.h:39:45

```
typedef struct {
ca_aes_mode_t      mode;
ca_aes_keysize_t   keysize;
u32 key[8];       /* max 256-bit = 8 words */
u32 iv[4];        /* IV = 4 words (CBC/CTR) */
bool configured;
} ca_aes_ctx_t;
```

A configuration structure used to store the state and parameters for AES hardware encryption/decryption operations.

Membri:

Nome	Tipo	Descrizione
`mode`	`ca_aes_mode_t`	Defines the AES operation mode (e.g., ECB, CBC). Must be set before calling initialization functions.
`keysize`	`ca_aes_keysize_t`	Specifies the bit-length of the key (128, 192, or 256 bits). Must match the data provided in the key array.
`key`	`u32[8]`	The secret key buffer. Only the required number of words based on keysize are used.
`iv`	`u32[4]`	Initialization Vector for modes like CBC or CTR. Ignored for ECB mode.
`configured`	`bool`	Internal flag used by the driver to verify if the context has been properly initialized. Do not modify manually.

Note:
The structure is typically allocated by the user on the stack or as a global variable. It must be passed to the AES driver initialization function before any encryption or decryption calls. The driver does not own the memory; the user is responsible for its lifecycle.

Uso:
Use this struct to define the cryptographic parameters for a session. Pass a pointer to this struct to the AES driver's setup and processing functions to perform secure data transformations.

Esempio:

```
ca_aes_ctx_t aes_ctx = {0};
aes_ctx.mode = CA_AES_MODE_CBC;
aes_ctx.keysize = CA_AES_KEYSIZE_128;
memcpy(aes_ctx.key, my_secret_key, 16);
memcpy(aes_ctx.iv, my_iv, 16);
ca_aes_init(&aes_ctx);
```

---

ca_aes_iv_gen_cb_t

Tipo: Callback
File: `caos/crypto/inc/aes_channel_service.h:27:27`

```
typedef void (*ca_aes_iv_gen_cb_t)(u8 iv[AES_CH_IV_SIZE], void *user)
```

A callback function type used to generate a unique Initialization Vector (IV) for AES encryption operations.

Membri:

Nome	Tipo	Descrizione
iv	u8[AES_CH_IV_SIZE]	A buffer of size AES_CH_IV_SIZE (typically 16 bytes) where the generated IV must be written. Must not be null.
user	void *	A pointer to user-defined context data passed through from the registration function. Can be NULL if no context is needed.

Note:
This callback is invoked by the AES channel service whenever a new IV is required for a cryptographic operation. The implementation must ensure the IV is cryptographically strong (e.g., using a hardware random number generator). The caller of the AES service owns the memory pointed to by the 'user' parameter. The callback must be thread-safe if the AES service is accessed from multiple tasks.

Uso:
Used when configuring an AES channel via the service API. You provide a pointer to a function matching this signature to allow the system to request a fresh IV for each encryption block or session.

Esempio:

```
static void my_iv_generator(u8 iv[AES_CH_IV_SIZE], void *user) {
    // Fill the IV buffer with random data from the hardware RNG
    for (int i = 0; i < AES_CH_IV_SIZE; i++) {
        iv[i] = (u8)(rand() & 0xFF);
    }
}

// Usage in configuration
ca_aes_config_t config = {
    .iv_gen_cb = my_iv_generator,
    .user_data = NULL
};
```

---

ca_aes_key_ratchet_cb_t

Tipo: Callback
File: caos/crypto/inc/aes_channel_service.h:34:34

```
typedef bool (*ca_aes_key_ratchet_cb_t)(u8 *key, u32 key_len, void *user
    )
```

A callback function type used to update or rotate an AES encryption key dynamically during a secure session.

Membri:

Nome	Tipo	Descrizione
key	u8 *	Pointer to the buffer where the new key material should be written. Must not be NULL.
key_len	u32	The size of the key buffer in bytes. Ensure the written key does not exceed this length to prevent buffer overflows.
user	void *	A user-defined context pointer passed through from the registration function, typically used to access session state or configuration.

Note:
This callback is invoked by the AES service when a key rotation event is triggered. The function must return 'true' if the key was successfully updated, or 'false' to indicate a failure, which will likely halt the cryptographic operation. Ensure the implementation is thread-safe if the AES service is accessed from multiple tasks.

Uso:
Used when configuring an AES channel that requires periodic key updates (ratcheting) for forward secrecy. It is registered during the initialization of the AES channel service.

Esempio:

```
static bool my_key_ratchet_handler(u8 *key, u32 key_len, void *user) {
    // Example: Derive a new key using a simple XOR or KDF
    for (u32 i = 0; i < key_len; i++) {
        key[i] ^= 0xAA;
    }
    return true;
}

// Usage in service configuration
ca_aes_channel_cfg_t cfg = {
    .ratchet_cb = my_key_ratchet_handler,
    .user_data = NULL
};
```

`ca_aes_keysize_t`

Tipo: Enumerazione
File: `caos/drivers/inc/aes.h:32:36`

```
typedef enum {
AES_KEY_128 = 0,    /* KEYSIZE = 00 */
AES_KEY_192 = 1,    /* KEYSIZE = 01 */
AES_KEY_256 = 2,    /* KEYSIZE = 10 */
} ca_aes_keysize_t;
```

An enumeration defining the supported bit-lengths for AES encryption keys in the caOS hardware abstraction layer.

Membri:

Nome	Tipo	Descrizione
`CA_AES_KEY_128`	enum constant	Configures the AES engine for 128-bit keys. Valid value: 0.
`CA_AES_KEY_192`	enum constant	Configures the AES engine for 192-bit keys. Valid value: 1.
`CA_AES_KEY_256`	enum constant	Configures the AES engine for 256-bit keys. Valid value: 2.

Note:
This enum is used to program the hardware registers of the STM32 AES peripheral. Ensure the key buffer provided to the driver matches the size selected here; providing a buffer smaller than the selected key size will lead to memory corruption or undefined hardware behavior.

Uso:
Used as a parameter in AES initialization or configuration functions to specify the security strength of the encryption operation.

Esempio:

```c
ca_aes_keysize_t my_key_size = CA_AES_KEY_256;

// Example usage in a hypothetical driver configuration
void setup_encryption(void) {
    ca_aes_config_t config;
    config.key_size = my_key_size;
    // Proceed to initialize the AES peripheral with the selected size
}
```

---

ca_aes_mode_t

Tipo: Enumerazione
File: `caos/drivers/inc/aes.h:25:30`

```c
typedef enum {
AES_MODE_ECB = 0,
AES_MODE_CBC = 1,
AES_MODE_CTR = 2,
AES_MODE_GCM = 3,
} ca_aes_mode_t;
```

An enumeration defining the cryptographic operation modes available for the hardware AES peripheral.

Membri:

Nome	Tipo	Descrizione
`CA_AES_MODE_ECB`	`enum constant`	Electronic Codebook mode. Simplest mode, encrypts blocks independently. Not recommended for long messages due to pattern leakage.
`CA_AES_MODE_CBC`	`enum constant`	Cipher Block Chaining mode. Uses an Initialization Vector (IV) to chain blocks. Requires padding for data not aligned to block size.
`CA_AES_MODE_CTR`	`enum constant`	Counter mode. Turns a block cipher into a stream cipher. Does not require padding.
`CA_AES_MODE_GCM`	`enum constant`	Galois/Counter Mode. Provides both encryption and authentication (AEAD). Recommended for secure communication.

Note:
This enum is used to configure the AES hardware engine. Ensure the selected mode is supported by the specific STM32 hardware variant being used. Incorrect mode selection will result in decryption failure or invalid authentication tags.

Uso:
Pass this value to the AES initialization or configuration functions to set the operational mode before starting a cryptographic operation.

Esempio:

```c
ca_aes_config_t config;
config.mode = CA_AES_MODE_GCM;
config.key_size = CA_AES_KEY_128;
// Proceed to initialize the AES peripheral with the selected mode
ca_aes_init(&config);
```

---

ca_arp_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:83:86

```
typedef struct {
u32 renew_ms;   /* ARP cache entry lifetime in ms (0 = no cache) */
u8  cache_size; /* number of entries in static ARP cache (0 = disabled)
   */
} ca_arp_cfg_t;
```

Configuration structure for the Address Resolution Protocol (ARP) cache settings in the caOS network stack.

Membri:

Nome	Tipo	Descrizione
renew_ms	u32	The duration in milliseconds before an ARP cache entry is considered stale and requires renewal. Set to 0 to disable caching entirely.
cache_size	u8	The maximum number of static ARP entries the system can store. Set to 0 to disable the ARP cache feature.

Note:
This structure is typically passed as part of a larger network configuration object during system initialization. It is usually allocated in static memory or on the stack during the boot sequence. The user is responsible for ensuring these values are set before the network stack is started.

Uso:
Use this struct when configuring the network interface parameters in the caOS stack. It defines how the system manages IP-to-MAC address mappings to optimize network traffic.

Esempio:

```
ca_arp_cfg_t arp_config = { .renew_ms = 60000, .cache_size = 10 };
```

---

ca_arp_frame_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:91:101

```
typedef struct {
u16    htype;   /* hardware type = ARP_HTYPE_ETH big-endian */
u16    ptype;   /* protocol type = ARP_PTYPE_IP  big-endian */
u8     hlen;    /* hardware address length = 6 */
u8     plen;    /* protocol address length = 4 */
u16    oper;    /* ARP_OP_REQUEST / ARP_OP_REPLY big-endian */
ca_mac_t  sha;     /* sender hardware address */
ca_ipv4_t spa;     /* sender protocol address */
ca_mac_t  tha;     /* target hardware address */
ca_ipv4_t tpa;     /* target protocol address */
} __attribute__((packed)) ca_arp_frame_t;
```

Represents the structure of an ARP (Address Resolution Protocol) packet used for mapping hardware addresses to network addresses.

Membri:

Nome	Tipo	Descrizione
`htype`	`u16`	Hardware type. Must be set to ARP_HTYPE_ETH (0x0001) in big-endian format.
`ptype`	`u16`	Protocol type. Must be set to ARP_PTYPE_IP (0x0800) in big-endian format.
`hlen`	`u8`	Hardware address length. For Ethernet, this is always 6.
`plen`	`u8`	Protocol address length. For IPv4, this is always 4.
`oper`	`u16`	Operation code. Use ARP_OP_REQUEST (1) or ARP_OP_REPLY (2) in big-endian format.
`sha`	`ca_mac_t`	Sender hardware address (MAC address of the device sending the packet).
`spa`	`ca_ipv4_t`	Sender protocol address (IP address of the device sending the packet).
`tha`	`ca_mac_t`	Target hardware address (MAC address of the destination device).
`tpa`	`ca_ipv4_t`	Target protocol address (IP address of the destination device).

Note:
The struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, which is critical for network protocol compliance. All multi-byte fields must be stored in big-endian (network byte order).

Uso:
Used when manually constructing or parsing raw ARP packets in the network stack layer. Typically populated before passing the buffer to the Ethernet driver's transmit function.

Esempio:

```
ca_arp_frame_t arp_pkt;

arp_pkt.htype = htons(ARP_HTYPE_ETH);
arp_pkt.ptype = htons(ARP_PTYPE_IP);
arp_pkt.hlen = 6;
arp_pkt.plen = 4;
arp_pkt.oper = htons(ARP_OP_REQUEST);

// Populate addresses
memcpy(arp_pkt.sha, my_mac, 6);
memcpy(arp_pkt.spa, my_ip, 4);
memset(arp_pkt.tha, 0, 6); // Target MAC unknown in request
memcpy(arp_pkt.tpa, target_ip, 4);
```

`ca_barrier_t`

Tipo: Struttura
File: `caos/inc/sync.h:352:358`

```
typedef struct {
volatile u32  count;          /* number of tasks to synchronize */
volatile u32  arrived;        /* tasks arrived at the barrier in this
   phase */
volatile u32  phase;          /* current phase (auto-incremented) */
ca_wait_queue_t   wait_queue;
```

```
ca_spinlock_irq_t internal_lock;
} ca_barrier_t;
```

A synchronization primitive that forces a group of tasks to wait until a specific number of tasks have reached the barrier point.

Membri:

Nome	Tipo	Descrizione
`count`	`u32`	The total number of tasks required to release the barrier. Must be greater than zero.
`arrived`	`u32`	Internal counter tracking how many tasks have currently reached the barrier. Do not modify manually.
`phase`	`u32`	Internal counter used to distinguish between different synchronization cycles. Do not modify manually.
`wait_queue`	`ca_wait_queue_t`	The internal queue where tasks are blocked while waiting for the barrier to be satisfied.
`internal_lock`	`ca_spinlock_irq_t`	A spinlock used to ensure atomic access to the barrier's internal state during synchronization.

Note:
The barrier must be initialized before use. It is typically allocated in the global data segment or on the heap by the application. Ownership is held by the application, but the RTOS kernel manages the internal state during wait/signal operations. Ensure 'count' is set correctly during initialization, as an incorrect value can lead to permanent task blocking (deadlock).

Uso:
Use this when you need to coordinate multiple parallel tasks to reach a common execution point before any of them can proceed to the next stage of processing.

Esempio:

```
ca_barrier_t my_barrier;

void init_sync(void) {
    my_barrier.count = 3;
    my_barrier.arrived = 0;
    my_barrier.phase = 0;
    ca_wait_queue_init(&my_barrier.wait_queue);
    ca_spinlock_irq_init(&my_barrier.internal_lock);
}

void task_worker(void *arg) {
    /* Perform work */
    ca_barrier_wait(&my_barrier);
    /* Proceed only after 3 tasks have reached this point */
}
```

`ca_block_pool_t`

Tipo: Struttura
File: `caos/inc/block_pool.h:38:44`

```
typedef struct {
void          *free_list;   /* first free block (in-place linked list) */
u32            block_size;  /* size of each block (>= 4, multiple of 4)
   */
```

```
u32            total;       /* total number of blocks */
volatile u32   free_count;  /* currently free blocks */
ca_spinlock_irq_t lock;        /* ISR-safe spinlock */
} ca_block_pool_t;
```

A fixed-size memory block allocator that provides O(1) allocation and deallocation for objects of identical size.

Membri:

Nome	Tipo	Descrizione
`free_list`	`void *`	Pointer to the first available memory block. Managed internally as a linked list.
`block_size`	`u32`	Size of each individual block in bytes. Must be at least 4 and a multiple of 4.
`total`	`u32`	Total number of blocks available in the pool.
`free_count`	`volatile u32`	Current number of available blocks. Updated atomically.
`lock`	`ca_spinlock_irq_t`	Spinlock used to ensure thread-safe and ISR-safe access to the pool.

Note:
The pool must be initialized using ca_block_pool_init before use. The memory buffer provided to the pool must be aligned to 4 bytes. The structure itself is typically allocated in static memory or as part of a larger control block. Ownership of the memory remains with the pool; users must return blocks using ca_block_free to prevent leaks.

Uso:
Use this when you need to frequently allocate and free objects of the same size (e.g., network packets or message buffers) to avoid heap fragmentation. Use ca_block_alloc to retrieve a block and ca_block_free to return it.

Esempio:

```
#include "caos/inc/block_pool.h"

#define POOL_SIZE 10
#define BLOCK_SIZE 64

static ca_block_pool_t my_pool;
static u8 pool_buffer[POOL_SIZE * BLOCK_SIZE];

void init_system(void) {
    /* Initialize the pool with the buffer and parameters */
    ca_block_pool_init(&my_pool, pool_buffer, BLOCK_SIZE, POOL_SIZE);
}

void task_process(void) {
    void *ptr = ca_block_alloc(&my_pool);
    if (ptr != NULL) {
        /* Use the block for data processing */
        ca_memzero(ptr, BLOCK_SIZE);

        /* Return the block to the pool */
        ca_block_free(&my_pool, ptr);
    }
}
```

ca_can_cfg_t

Tipo: Struttura
File: caos/drivers/inc/can.h:24:29

```
typedef struct {
u8  can_num;    /* 1 = CAN1/FDCAN1, 2 = CAN2/FDCAN2 */
u32 baudrate;   /* 125000 | 250000 | 500000 | 1000000 */
bool loopback;  /* true = test loopback interno */
bool silent;    /* true = listen-only (bus monitoring) */
} ca_can_cfg_t;
```

Configuration structure used to initialize a CAN peripheral interface in caOS.

Membri:

Nome	Tipo	Descrizione
can_num	u8	The hardware peripheral index. Use 1 for CAN1/FDCAN1 or 2 for CAN2/FDCAN2. Invalid values may cause hardware initialization failure.
baudrate	u32	The communication speed in bits per second. Supported values are 125000, 250000, 500000, or 1000000. Incorrect values will result in bus errors.
loopback	bool	Enables internal loopback mode for testing. If true, transmitted frames are received internally and not sent to the physical bus.
silent	bool	Enables listen-only mode. If true, the controller receives messages but does not acknowledge them or transmit, useful for bus monitoring.

Note:
This struct is typically passed by pointer to the driver initialization function. It is usually allocated on the stack before calling the init function. Ensure all fields are explicitly set to avoid undefined behavior from uninitialized memory.

Uso:
Use this struct to define the operating parameters of a CAN bus before calling the driver's initialization function. It is the standard way to configure hardware settings without hardcoding values in the driver logic.

Esempio:

```
ca_can_cfg_t can_config = {
    .can_num = 1,
    .baudrate = 500000,
    .loopback = false,
    .silent = false
};

/* Pass the address of the struct to the driver init function */
ca_can_init(&can_config);
```

---

ca_can_frame_t

Tipo: Struttura
File: caos/drivers/inc/can.h:31:37

```c
typedef struct {
u32  id;       /* 11-bit (ide=false) or 29-bit (ide=true) */
bool ide;      /* false = standard frame, true = extended */
bool rtr;      /* true = remote frame */
u8   dlc;      /* number of valid bytes in data[], 0-8 */
u8   data[8];
} ca_can_frame_t;
```

Represents a single CAN bus data frame used for transmitting or receiving messages.

Membri:

Nome	Tipo	Descrizione
`id`	`u32`	The CAN message identifier. Use 11 bits for standard frames or 29 bits for extended frames.
`ide`	`bool`	Identifier Extension bit. Set to false for 11-bit standard IDs, true for 29-bit extended IDs.
`rtr`	`bool`	Remote Transmission Request. Set to true to request data from another node, false for standard data frames.
`dlc`	`u8`	Data Length Code. Specifies the number of valid bytes in the data array. Must be between 0 and 8.
`data`	`u8[8]`	The payload buffer containing up to 8 bytes of data.

Note:
This struct is typically allocated on the stack by the application. It does not require dynamic memory allocation. Ensure dlc is set correctly, as the hardware will ignore bytes beyond the specified length.

Uso:
Used as a parameter in CAN driver functions to define the content of a message to be sent or to store a received message.

Esempio:

```c
ca_can_frame_t frame = {0};
frame.id = 0x123;
frame.ide = false;
frame.rtr = false;
frame.dlc = 2;
frame.data[0] = 0xAA;
frame.data[1] = 0xBB;
ca_can_send(CAN1, &frame);
```

`ca_caos_config_status`

Tipo: Struttura
File: `caos/inc/caos_info.h:9:175`

```c
typedef struct {
/* --- I/O subsystems (os_config.h) --- */
u8  itm;
u8  dbg_uart;
u8  uart;
/* USB */
u8  usb;
u8  usb_cdc;
u8  usb_msc;
```

```
u8  usb_ncm;
u8  usb_dfu;
/* stdout */
u8  stdout_en;

159 u16 mqtt_rx_buf_size;
160 u16 mqtt_keepalive_sec;
161 u32 modbus_timeout_ms;
162 u16 modbus_rx_buf_size;
163 u16 iperf_default_port;
164 u16 http_default_port;
165 u16 http_req_buf_size;
166 u16 http_resp_buf_size;
167 } ca_caos_config_status;
```

A structure containing the current configuration and status flags of the caOS RTOS environment.

Membri:

Nome	Tipo	Descrizione
`u8 fields (e.g., itm, usb, spi, net)`	`u8`	Boolean-like subsystem, p current build
`u32/u16/u8 numeric fields (e.g., sysclk_hz, max_task, stack_min)`	`u32/u16/u8`	Configuration clock frequen

Note:
This struct is typically populated by the system during initialization. It is read-only for the application layer; modifying these values at runtime will not change the actual hardware or OS configuration, as they reflect the static settings defined in os_config.h and objmap.h.

Uso:
Use this struct to inspect the system's capabilities or current configuration at runtime, especially when writing diagnostic tools, CLI commands, or generic drivers that need to adapt based on enabled features.

Esempio:

```
ca_caos_config_status config;

// Retrieve the current system configuration
if (caos_get_config(&config) == CA_OK) {
    if (config.usb_cdc) {
        // USB CDC is enabled, safe to initialize USB-related logging
        printf("USB CDC is active at %lu Hz\n", config.sysclk_hz);
    }
}
```

---

ca_cli_hook_t

Tipo: Callback
File: caos/inc/cli.h:189:189

```
typedef u16 (*ca_cli_hook_t)(c_str cmd)
```

A function pointer type used to define custom command handlers for the caOS Command Line Interface (CLI).

Membri:

Nome	Tipo	Descrizione
cmd	c_str	A pointer to the string containing the command arguments passed by the user. Must not be modified.
return value	u16	An integer status code. Typically 0 indicates success, while non-zero values represent specific error codes defined by the application.

Note:
The callback is executed within the context of the CLI task. Ensure the implementation is non-blocking and does not perform long-running operations to avoid starving other system tasks. The memory for the command string is managed by the CLI module and is only valid for the duration of the callback execution.

Uso:
Use this type when registering new commands in the CLI system. You define a function matching this signature and pass it to the CLI registration API to extend the shell functionality.

Esempio:

```
static u16 my_custom_cmd(c_str cmd) {
    if (cmd == NULL) return 1;
    // Process the command logic here
    return 0;
}

// Registration example
ca_cli_register_cmd("status", my_custom_cmd);
```

---

ca_cli_node_t

Tipo: Struttura
File: caos/inc/cli.h:59:62

```
typedef struct ca_cli_node {
bool (*handler)(c_str *cmd);  /* true = comando gestito */
struct ca_cli_node *next;
} ca_cli_node_t;
```

A linked-list node representing a single command entry in the caOS Command Line Interface (CLI) system.

Membri:

Nome	Tipo	Descrizione
handler	bool (*)(c_str *cmd)	Function pointer to the command logic. Must return true if the command was recognized and executed, false otherwise. If it returns false, the CLI engine will attempt to match the next node in the list.
next	ca_cli_node_t *	Pointer to the next command node in the linked list. Must be set to NULL for the last element to avoid memory access violations during traversal.

Note:
The structure is typically allocated statically in the application code to ensure it persists for the lifetime of the CLI. The developer is responsible for linking these nodes together to form a chain. The CLI engine traverses this list sequentially, so place frequently used commands at the beginning of the list for better performance.

Uso:
Used to register custom commands to the caOS CLI. You define a handler function, assign it to a node, and link it into the system's command list so the CLI can parse user input.

Esempio:

```
static bool my_cmd_handler(c_str *cmd) { if (c_str_cmp(cmd, "help") == 0) { /*
    handle help */ return true; } return false; } static ca_cli_node_t my_node =
     { .handler = my_cmd_handler, .next = NULL };
```

---

ca_condvar_t

Tipo: Struttura
File: caos/inc/sync.h:237:240

```
typedef struct {
ca_wait_queue_t wait_queue;       // Task waiting
ca_spinlock_irq_t  internal_lock; // Protects internal structure
} ca_condvar_t;
```

A condition variable used to block a task until a specific condition is met or a signal is received from another task.

Membri:

Nome	Tipo	Descrizione
`wait_queue`	`ca_wait_queue_t`	A list of tasks currently blocked on this condition variable. Do not modify this field directly.
`internal_lock`	`ca_spinlock_irq_t`	A spinlock used to ensure thread-safe access to the wait queue. Must be held during internal operations.

Note:
The condition variable must be initialized before use. It does not store state; it only provides a mechanism for tasks to wait for a signal. It is typically used in conjunction with a mutex to prevent race conditions when checking the condition.

Uso:
Use this when a task needs to wait for a specific event or data availability. It is used with ca_cond_wait() to block and ca_cond_signal() or ca_cond_broadcast() to wake up waiting tasks.

Esempio:

```
ca_condvar_t my_cond;

void init_system() {
    ca_cond_init(&my_cond);
}

void task_waiter() {
    ca_mutex_lock(&my_mutex);
    while (!data_ready) {
        ca_cond_wait(&my_cond, &my_mutex);
    }
    // Process data
    ca_mutex_unlock(&my_mutex);
}

void task_signaler() {
    ca_mutex_lock(&my_mutex);
    data_ready = 1;
    ca_cond_signal(&my_cond);
    ca_mutex_unlock(&my_mutex);
}
```

`ca_cordic_func_t`

Tipo: Enumerazione
File: `caos/drivers/inc/cordic.h:35:46`

```
typedef enum {
CA_CORDIC_COS = 0,
CA_CORDIC_SIN,
CA_CORDIC_PHASE,
CA_CORDIC_MODULUS,
CA_CORDIC_ATAN,
CA_CORDIC_COSH,
CA_CORDIC_SINH,
CA_CORDIC_ATANH,
CA_CORDIC_LN,
CA_CORDIC_SQRT
} ca_cordic_func_t;
```

Enumeration defining the mathematical operations supported by the hardware CORDIC co-processor.

Membri:

Nome	Tipo	Descrizione
CA_CORDIC_COS	enum	Calculates the cosine of the input angle.
CA_CORDIC_SIN	enum	Calculates the sine of the input angle.
CA_CORDIC_PHASE	enum	Calculates the phase (arctangent) of a complex number (x, y).
CA_CORDIC_MODULUS	enum	Calculates the magnitude (modulus) of a complex number (x, y).
CA_CORDIC_ATAN	enum	Calculates the arctangent of the input value.
CA_CORDIC_COSH	enum	Calculates the hyperbolic cosine.
CA_CORDIC_SINH	enum	Calculates the hyperbolic sine.
CA_CORDIC_ATANH	enum	Calculates the hyperbolic arctangent.
CA_CORDIC_LN	enum	Calculates the natural logarithm.
CA_CORDIC_SQRT	enum	Calculates the square root.

Note:
This enum is used to configure the CORDIC hardware peripheral. Ensure the CORDIC unit is initialized via ca_cordic_init before performing calculations. The hardware expects specific input formats (typically Q1.31 fixed-point) depending on the selected function.

Uso:
Used as a parameter in the ca_cordic_calc function to specify which mathematical operation the hardware should execute on the provided input data.

Esempio:

```c
#include "caos/drivers/inc/cordic.h"

void perform_math(void) {
    int32_t input = 1073741824; // Example Q1.31 value
    int32_t result = 0;

    // Initialize the CORDIC hardware
    ca_cordic_init();

    // Perform a square root calculation using the CORDIC unit
    // ca_cordic_calc(function, input_value, &output_pointer)
    ca_cordic_calc(CA_CORDIC_SQRT, input, &result);
}
```

---

ca_dac_comp_hyst_t

Tipo: Enumerazione
File: caos/drivers/inc/dac.h:46:51

```c
typedef enum {
CA_DAC_COMP_HYST_NONE = 0,
CA_DAC_COMP_HYST_LOW,
CA_DAC_COMP_HYST_MEDIUM,
CA_DAC_COMP_HYST_HIGH
} ca_dac_comp_hyst_t;
```

Defines the hysteresis level for the DAC internal comparator, used to prevent signal noise from triggering false state changes.

Membri:

Nome	Tipo	Descrizione
`CA_DAC_COMP_HYST_NONE`	`enum value`	No hysteresis applied. The comparator is highly sensitive to noise.
`CA_DAC_COMP_HYST_LOW`	`enum value`	Low hysteresis level. Suitable for signals with minimal noise.
`CA_DAC_COMP_HYST_MEDIUM`	`enum value`	Medium hysteresis level. Balanced setting for general use.
`CA_DAC_COMP_HYST_HIGH`	`enum value`	High hysteresis level. Best for noisy environments to ensure stable switching.

Note:
This enum is passed to the DAC configuration functions to tune the hardware comparator. It is a simple integer-based enum, so no memory allocation or lifecycle management is required by the user.

Uso:
Use this type when configuring the DAC comparator via ca_dac_comp_init or updating the level dynamically using ca_dac_comp_level.

Esempio:

```c
#include "caos/drivers/inc/dac.h"

void setup_dac_comparator(void) {
    /* Initialize the DAC comparator with medium hysteresis */
    ca_dac_comp_init(CA_DAC_COMP_HYST_MEDIUM);

    /* Later, if noise increases, update the hysteresis level */
    ca_dac_comp_level(CA_DAC_COMP_HYST_HIGH);
}
```

`ca_dac_config_t`

Tipo: Struttura
File: `caos/drivers/inc/dac.h:24:26`

```c
typedef struct {
u8 channel;   /* 1 = CH1 (PA4), 2 = CH2 (PA5) */
} ca_dac_config_t;
```

Configuration structure used to specify which hardware DAC channel to initialize on the STM32.

Membri:

Nome	Tipo	Descrizione
`channel`	`u8`	The DAC channel index. Use 1 for CH1 (mapped to PA4) or 2 for CH2 (mapped to PA5). Providing any other value may result in undefined behavior or initialization failure.

Note:
This structure is typically passed by value or pointer to the DAC initialization function. It does not require dynamic allocation and should be defined in the scope where the driver is being configured.

Uso:

Use this struct when preparing to initialize the DAC peripheral. It acts as a parameter for the driver setup function to inform the system which physical pin and internal DAC register set to enable.

Esempio:

```
ca_dac_config_t dac_cfg;
dac_cfg.channel = 1;
ca_dac_init(&dac_cfg);
```

---

ca_dhcp_bound_cb_t

Tipo: Callback
File: caos/net/inc/dhcp_service.h:81:81

```
typedef void (*ca_dhcp_bound_cb_t)(ca_ipv4_t ip, ca_ipv4_t mask,
```

A callback function type triggered by the DHCP service when an IP address lease is successfully obtained or renewed.

Membri:

Nome	Tipo	Descrizione
ip	ca_ipv4_t	The IPv4 address assigned to the device by the DHCP server. Must be treated as a read-only value.
mask	ca_ipv4_t	The subnet mask associated with the assigned IP address. Used to define the local network boundary.

Note:
This callback is executed within the context of the DHCP service task. It must be kept short and non-blocking to avoid delaying network stack processing. The user is responsible for storing these values if they are needed outside the callback scope, as the parameters are passed by value.

Uso:
Used when registering a DHCP client instance. You assign a function pointer of this type to the DHCP configuration structure to receive notification of network configuration changes.

Esempio:

```
void my_dhcp_callback(ca_ipv4_t ip, ca_ipv4_t mask) {
    printf("DHCP Bound! IP: %u.%u.%u.%u\n", ip.addr[0], ip.addr[1], ip.addr[2],
    ip.addr[3]);
}

// Usage in configuration
ca_dhcp_config_t config = {
    .bound_cb = my_dhcp_callback
};
```

---

ca_dhcp_bound_t

Tipo: Callback
File: caos/net/inc/net_cfg.h:101:101

```
typedef void (*ca_dhcp_bound_t)(ca_ipv4_t ip, ca_ipv4_t mask, ca_ipv4_t
    gw, ca_ipv4_t dns)
```

A callback function type triggered by the DHCP client when an IP address lease is successfully obtained or renewed.

Membri:

Nome	Tipo	Descrizione
ip	ca_ipv4_t	The IPv4 address assigned to the device by the DHCP server.
mask	ca_ipv4_t	The subnet mask provided by the DHCP server to define the local network range.
gw	ca_ipv4_t	The default gateway (router) IP address for external network communication.
dns	ca_ipv4_t	The primary DNS server IP address provided by the DHCP server.

Note:
This callback is executed within the context of the network stack task. It must be non-blocking and should not perform heavy processing or wait on semaphores/mutexes to avoid stalling network traffic. The user is responsible for storing these values if they need to be accessed outside the callback scope.

Uso:
Used during the initialization of the DHCP client module. You assign a function pointer of this type to the DHCP configuration structure to receive notification once the network interface is fully configured.

Esempio:

```
void my_dhcp_callback(ca_ipv4_t ip, ca_ipv4_t mask, ca_ipv4_t gw, ca_ipv4_t dns)
    {
    printf("Network configured! IP: %u.%u.%u.%u\n", ip[0], ip[1], ip[2], ip[3]);
}

// In your network initialization code:
ca_dhcp_config_t config;
config.on_bound = my_dhcp_callback;
ca_dhcp_start(&config);
```

---

ca_dhcp_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:102:105

```
typedef struct {
u32             timeout_ms;  /* discover timeout (0 = 5000 ms default)
   */
ca_dhcp_bound_t on_bound;    /* called when IP is assigned (may be NULL)
    */
} ca_dhcp_cfg_t;
```

Configuration structure used to define the behavior and callback for the caOS DHCP client.

Membri:

Nome	Tipo	Descrizione
timeout_ms	u32	Time in milliseconds to wait for a DHCP offer. If set to 0, the system defaults to 5000ms.
on_bound	ca_dhcp_bound_t	A function pointer to a callback executed once the DHCP server assigns an IP address. Can be set to NULL if no notification is required.

Note:
The structure is typically passed by value or pointer to the DHCP initialization function. It does not require dynamic allocation; it can be declared on the stack or as a global configuration object. Ensure the callback function is thread-safe as it may be executed from the network stack context.

Uso:
Use this structure when initializing the network interface to enable dynamic IP assignment. It is passed as an argument to the DHCP configuration API to customize the handshake timeout and define the application-level logic that triggers once the network is ready.

Esempio:

```
void my_on_bound_callback(u32 ip_addr) { /* Handle IP assignment */ }

ca_dhcp_cfg_t dhcp_cfg = {
    .timeout_ms = 3000,
    .on_bound = my_on_bound_callback
};

ca_net_dhcp_start(&dhcp_cfg);
```

`ca_dhcp_expire_cb_t`

Tipo: Callback
File: `caos/net/inc/dhcp_service.h:88:88`

```
typedef void (*ca_dhcp_expire_cb_t)(void)
```

A callback function type triggered when a DHCP lease expires, used to notify the application that the IP address is no longer valid.

Membri:

Nome	Tipo	Descrizione
`void`	`void`	The callback takes no arguments and returns nothing.

Note:
This callback is executed within the context of the DHCP service task. It must be kept short and non-blocking to avoid delaying network stack operations. The user is responsible for implementing logic to handle the loss of network connectivity, such as re-initializing the network interface or stopping dependent services.

Uso:
Use this type when configuring the DHCP service to monitor lease status. It is typically assigned during the initialization phase of the network stack to ensure the application can react gracefully when the assigned IP address is revoked.

Esempio:

```
void my_dhcp_expire_handler(void) { /* Log the event or signal the main loop to
    stop network tasks */ } ... ca_dhcp_config_t config = { .expire_cb =
    my_dhcp_expire_handler };
```

---

ca_dhcp_offer_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:358:370

```
typedef struct {
ca_ipv4_t offered_ip;   /* yiaddr     IP offered by server */
ca_ipv4_t server_ip;    /* siaddr     next-server IP (may be 0) */
ca_ipv4_t server_id;    /* option 54     Server Identifier (use for
   REQUEST) */
ca_ipv4_t subnet_mask;  /* option 1 */
ca_ipv4_t gateway;      /* option 3 (first router) */
ca_ipv4_t dns;          /* option 6 (first DNS) */
ca_ipv4_t ntp_server;   /* option 42 (first NTP server); 0 if not
   present */
u32    lease_time;   /* option 51, seconds */
u32    t1;           /* option 58, seconds; 0 = use lease/2 */
u32    t2;           /* option 59, seconds; 0 = use lease*7/8 */
u8     msg_type;     /* DHCP_MSG_OFFER / DHCP_MSG_ACK / DHCP_MSG_NAK */
} ca_dhcp_offer_t;
```

A structure containing the network configuration parameters received from a DHCP server during the DORA process.

Membri:

Nome	Tipo	Descrizione
offered_ip	ca_ipv4_t	The IP address assigned to this client by the DHCP server.
server_ip	ca_ipv4_t	The IP address of the next server to use in bootstrap; often 0 if not applicable.
server_id	ca_ipv4_t	The unique identifier of the DHCP server (Option 54). Must be included in the subsequent DHCP REQUEST packet.
subnet_mask	ca_ipv4_t	The subnet mask for the network (Option 1).
gateway	ca_ipv4_t	The default gateway IP address (Option 3).
dns	ca_ipv4_t	The primary DNS server IP address (Option 6).
ntp_server	ca_ipv4_t	The primary NTP server IP address (Option 42). Set to 0 if the server did not provide one.
lease_time	u32	The duration of the IP lease in seconds (Option 51).
t1	u32	Renewal time (T1) in seconds. If 0, the stack defaults to lease_time / 2.
t2	u32	Rebinding time (T2) in seconds. If 0, the stack defaults to lease_time * 7 / 8.
msg_type	u8	The DHCP message type (e.g., DHCP_MSG_OFFER, DHCP_MSG_ACK, DHCP_MSG_NAK).

Note:
This structure is typically populated by the caOS network stack when a DHCP response is parsed. The application should treat this as read-only data provided by the stack. Ensure the memory is not modified while the DHCP state machine is processing the offer.

Uso:
Used by the application to inspect the network configuration offered by a DHCP server before accepting it or to verify the parameters after a successful DHCP ACK.

Esempio:

```
ca_dhcp_offer_t my_offer;

// Assuming the stack has populated the offer structure
if (my_offer.msg_type == DHCP_MSG_OFFER) {
    printf("Received IP: %d.%d.%d.%d\n",
           (my_offer.offered_ip >> 24) & 0xFF,
           (my_offer.offered_ip >> 16) & 0xFF,
           (my_offer.offered_ip >> 8) & 0xFF,
           my_offer.offered_ip & 0xFF);
}
```

---

ca_dma2d_am_t

Tipo: Enumerazione
File: caos/drivers/inc/dma2d.h:66:70

```
typedef enum {
CA_DMA2D_ALPHA_KEEP = 0,     /* the pixel's own (0xFF without an alpha
    channel) */
CA_DMA2D_ALPHA_REPLACE,      /* `alpha` */
CA_DMA2D_ALPHA_MULT          /* pixel alpha * `alpha` / 255 */
} ca_dma2d_am_t;
```

Defines how the DMA2D engine handles pixel alpha blending during image copy or conversion operations.

Membri:

Nome	Tipo	Descrizione
CA_DMA2D_ALPHA_KEEP	enum value	Uses the pixel's original alpha value (or 0xFF if no alpha channel exists). No blending is applied.
CA_DMA2D_ALPHA_REPLACE	enum value	Replaces the pixel's alpha value with a constant alpha value provided in the configuration.
CA_DMA2D_ALPHA_MULT	enum value	Calculates the new alpha as (pixel_alpha * constant_alpha) / 255. Used for fading or transparency effects.

Note:
This enum is used as a parameter in DMA2D configuration structures. It determines the mathematical operation performed on the alpha channel of pixels during hardware-accelerated transfers. Ensure the destination format supports alpha if using MULT or REPLACE modes.

Uso:
Used when configuring DMA2D blending parameters, typically passed to functions like ca_dma2d_blend or ca_dma2d_copy to define how source pixels interact with the destination buffer.

Esempio:

```
ca_dma2d_am_t alpha_mode = CA_DMA2D_ALPHA_MULT;
/* Assuming a buffer structure is prepared for a blend operation */
/* The following function call uses the alpha mode to blend two images */
ca_dma2d_blend(src_addr, dst_addr, width, height, alpha_mode,
    constant_alpha_value);
```

---

ca_dma2d_dst_t

Tipo: Struttura
File: caos/drivers/inc/dma2d.h:89:94

```
typedef struct {
void            *addr;        /* first pixel of the rectangle */
u32              stride;      /* pixels per line of the whole image */
ca_dma2d_fmt_t   fmt;         /* CA_DMA2D_ARGB8888..ARGB4444 */
u8               flags;       /* CA_DMA2D_AI | _RBS */
} ca_dma2d_dst_t;
```

Defines the destination buffer properties for DMA2D graphics operations, such as memory address, layout, and pixel format.

Membri:

Nome	Tipo	Descrizione
addr	void *	Pointer to the memory location of the first pixel of the destination rectangle. Must be aligned according to hardware requirements.
stride	u32	The number of pixels per line for the entire image buffer, not just the rectangle being drawn. Used to calculate the memory offset for the next row.
fmt	ca_dma2d_fmt_t	The pixel format of the destination buffer (e.g., ARGB8888, RGB565). Must match the hardware configuration of the display or buffer.
flags	u8	Configuration flags for the operation. CA_DMA2D_AI (Alpha Inversion) or CA_DMA2D_RBS (Red-Blue Swap) can be applied.

Note:
This struct is typically allocated on the stack by the caller before passing it to DMA2D functions. The user is responsible for ensuring the memory pointed to by 'addr' is valid and large enough to hold the operation's output. The 'stride' must be correctly set to the full width of the image buffer to avoid memory corruption during multi-line operations.

Uso:
Used as an input parameter in ca_dma2d_copy, ca_dma2d_fill, or ca_dma2d_blend functions to define where the processed pixel data should be written.

Esempio:

```
ca_dma2d_dst_t dst = {0};
dst.addr = (void *)0xD0000000; // Framebuffer start address
dst.stride = 800;              // Full width of the display
dst.fmt = CA_DMA2D_ARGB8888;
dst.flags = 0;

// Perform a fill operation using the defined destination
// ca_dma2d_fill(..., &dst, ...);
```

---

ca_dma2d_fmt_t

Tipo: Enumerazione
File: caos/drivers/inc/dma2d.h:49:61

```
typedef enum {
CA_DMA2D_ARGB8888 = 0,   /* input and output */
CA_DMA2D_RGB888,         /* input and output, 3 bytes */
CA_DMA2D_RGB565,         /* input and output */
CA_DMA2D_ARGB1555,       /* input and output */
CA_DMA2D_ARGB4444,       /* input and output */
CA_DMA2D_L8,             /* input: CLUT index */
CA_DMA2D_AL44,           /* input: alpha 4 + index 4 */
CA_DMA2D_AL88,           /* input: alpha 8 + index 8 */
CA_DMA2D_L4,             /* input: CLUT index, two per byte */
CA_DMA2D_A8,             /* input: alpha only, color fixed */
CA_DMA2D_A4              /* input: alpha only, two per byte */
} ca_dma2d_fmt_t;
```

Defines the pixel format for DMA2D (Chrom-ART) operations, specifying how color data is interpreted by the hardware.

Membri:

Nome	Tipo	Descrizione
CA_DMA2D_ARGB8888	enum	32-bit color: 8 bits each for Alpha, Red, Green, Blue.
CA_DMA2D_RGB888	enum	24-bit color: 8 bits each for Red, Green, Blue.
CA_DMA2D_RGB565	enum	16-bit color: 5 bits Red, 6 bits Green, 5 bits Blue.
CA_DMA2D_ARGB1555	enum	16-bit color: 1 bit Alpha, 5 bits each for R, G, B.
CA_DMA2D_ARGB4444	enum	16-bit color: 4 bits each for A, R, G, B.
CA_DMA2D_L8	enum	8-bit indexed color (CLUT).
CA_DMA2D_AL44	enum	8-bit: 4 bits Alpha, 4 bits index.
CA_DMA2D_AL88	enum	16-bit: 8 bits Alpha, 8 bits index.
CA_DMA2D_L4	enum	4-bit indexed color (two pixels per byte).
CA_DMA2D_A8	enum	8-bit Alpha channel only.
CA_DMA2D_A4	enum	4-bit Alpha channel only (two pixels per byte).

Note:
This enum is used to configure the DMA2D hardware registers. Ensure the format matches the source/destination buffer memory layout. Incorrect formats will result in corrupted graphical output or memory access violations.

Uso:
Used in ca_dma2d_init, ca_dma2d_copy, and ca_dma2d_fill functions to inform the DMA2D engine how to interpret the pixel data in the provided memory buffers.

Esempio:

```
#include "caos/drivers/inc/dma2d.h"

void setup_display_buffer(void) {
    /* Define the format for the frame buffer */
    ca_dma2d_fmt_t format = CA_DMA2D_RGB565;

    /* Initialize DMA2D hardware with the chosen format */
    ca_dma2d_init(format);

    /* Perform a copy operation using the configured format */
    /* ca_dma2d_copy(src, dst, x, y, w, h); */
}
```

ca_dma2d_src_t

Tipo: Struttura
File: caos/drivers/inc/dma2d.h:77:87

```
typedef struct {
const void     *addr;       /* first pixel of the rectangle */
u32             stride;     /* pixels per line of the whole image */
ca_dma2d_fmt_t  fmt;
ca_dma2d_am_t   am;
u8              alpha;      /* for REPLACE and MULT */
u8              flags;      /* CA_DMA2D_AI | _RBS | _CLUT_CPU */
u32             color;      /* 0xRRGGBB for A8/A4 */
const u32      *clut;       /* ARGB8888 entries for L8/L4/AL44/AL88,
   NULL = keep the loaded one */
u16             clut_n;     /* entries, 1..256 */
} ca_dma2d_src_t;
```

Defines the source image configuration for DMA2D hardware acceleration operations like blending or copying.

Membri:

Nome	Tipo	Descrizione
addr	const void *	Pointer to the memory address of the first pixel of the source rectangle.
stride	u32	Number of pixels per line in the source image buffer (including padding).
fmt	ca_dma2d_fmt_t	Pixel format of the source data (e.g., RGB565, ARGB8888).
am	ca_dma2d_am_t	Alpha mode: defines how the alpha channel is handled (e.g., constant, pixel-based, or combined).
alpha	u8	Constant alpha value used when the alpha mode is set to REPLACE or MULT.
flags	u8	Bitmask for hardware options: CA_DMA2D_AI (Alpha Inversion), _RBS (Red/Blue Swap), or _CLUT_CPU.
color	u32	Default color value (0xRRGGBB) used for A8/A4 formats.
clut	const u32 *	Pointer to the Color Look-Up Table (ARGB8888 entries). Set to NULL to reuse the previously loaded CLUT.
clut_n	u16	Number of entries in the CLUT, valid range is 1 to 256.

Note:
The struct is typically allocated on the stack by the caller. The DMA2D hardware reads directly from the provided 'addr'. Ensure the memory pointed to by 'addr' and 'clut' remains valid until the DMA2D operation is completed (use ca_dma2d_wait to ensure synchronization).

Uso:
Used as an input parameter in ca_dma2d_copy and ca_dma2d_blend functions to define the source image properties before triggering the hardware transfer.

Esempio:

```
ca_dma2d_src_t src = {0};
src.addr = my_image_buffer;
```

```
src.stride = 320;
src.fmt = CA_DMA2D_FMT_RGB565;
src.am = CA_DMA2D_AM_CONSTANT;
src.alpha = 255;

/* Perform a copy operation using the configured source */
ca_dma2d_copy(&src, &dst, 0, 0, 320, 240);
ca_dma2d_wait();
```

---

ca_dma_cb_t

Tipo: Callback
File: caos/drivers/inc/dma.h:131:131

```
typedef void (*ca_dma_cb_t)(void *arg)
```

A function pointer type used to define a callback function that executes when a DMA transfer completes.

Membri:

Nome	Tipo	Descrizione
arg	void *	A pointer to user-defined data or context. This is passed back to the callback function when the DMA interrupt triggers. If no context is needed, pass NULL.

Note:
The callback is executed within the context of the DMA interrupt service routine (ISR). Therefore, the function must be kept short, must not block, and should not call any RTOS functions that are not 'from-ISR' safe. The user is responsible for ensuring the memory pointed to by 'arg' remains valid until the callback is executed.

Uso:
Used when configuring a DMA channel via the caOS driver API. You assign a function matching this signature to the DMA configuration structure to handle asynchronous completion events, such as notifying a task that a buffer is ready for processing.

Esempio:

```
void my_dma_complete_handler(void *arg) { BaseType_t xHigherPriorityTaskWoken =
    pdFALSE; xSemaphoreGiveFromISR((SemaphoreHandle_t)arg, &
    xHigherPriorityTaskWoken); portYIELD_FROM_ISR(xHigherPriorityTaskWoken); }
    // Usage in setup: config.callback = my_dma_complete_handler; config.cb_arg
    = my_semaphore;
```

---

ca_dma_ch_t

Tipo: Struttura
File: caos/drivers/inc/dma.h:43:46

```
typedef struct {
u8 controller;  /* 1=DMA1, 2=DMA2, 3=BDMA (H7) / LPDMA (H5) */
u8 stream;      /* stream/channel index (0-based) */
} ca_dma_ch_t;
```

A structure representing a specific DMA hardware channel identifier used to configure and request DMA transfers.

Membri:

Nome	Tipo	Descrizione
`controller`	`u8`	The DMA controller index. Valid values: 1 for DMA1, 2 for DMA2, 3 for BDMA (H7) or LPDMA (H5). Incorrect values will cause hardware access faults.
`stream`	`u8`	The specific stream or channel index within the selected controller (0-based). Must match the hardware datasheet for the specific peripheral.

Note:
This struct is a simple descriptor and does not contain state information. It is typically passed by value to driver functions. The user is responsible for ensuring the controller/stream combination is valid for the specific STM32 chip being used.

Uso:
Used as an input parameter for DMA peripheral initialization and transfer request functions to specify which hardware resource the driver should claim.

Esempio:

```
ca_dma_ch_t my_dma_channel = { .controller = 1, .stream = 0 };

/* Example usage in a hypothetical driver setup */
ca_dma_init(my_dma_channel, DMA_PRIORITY_HIGH);
```

`ca_dma_dir_t`

Tipo: Enumerazione
File: `caos/drivers/inc/dma.h:54:57`

```
typedef enum {
DMA_DIR_M2P = 0,  /* memory     peripheral (TX) */
DMA_DIR_P2M = 1,  /* peripheral     memory  (RX) */
} ca_dma_dir_t;
```

An enumeration defining the data transfer direction for DMA operations in caOS.

Membri:

Nome	Tipo	Descrizione
`CA_DMA_DIR_M2P`	`enum constant`	Memory to Peripheral transfer. Used for transmission (TX) operations where data is read from RAM and sent to a hardware peripheral.
`CA_DMA_DIR_P2M`	`enum constant`	Peripheral to Memory transfer. Used for reception (RX) operations where data is read from a hardware peripheral and stored into RAM.

Note:
This enum is used to configure the DMA controller's data flow direction. Ensure the direction matches the hardware peripheral's capability (e.g., a UART TX register only supports M2P). Incorrect configuration will result in data not being transferred or potential bus errors.

Uso:

Used as a parameter in DMA configuration structures or initialization functions to specify the source and destination relationship for the DMA stream.

Esempio:

```
ca_dma_config_t config;
config.direction = CA_DMA_DIR_M2P;
config.buffer = my_tx_buffer;
config.size = sizeof(my_tx_buffer);
ca_dma_init(DMA1_STREAM0, &config);
```

---

ca_dma_width_t

Tipo: Enumerazione
File: caos/drivers/inc/dma.h:60:64

```
typedef enum {
DMA_WIDTH_8  = 0,  /* 8-bit      size in byte      */
DMA_WIDTH_16 = 1,  /* 16-bit     size in halfword   */
DMA_WIDTH_32 = 2,  /* 32-bit     size in word       */
} ca_dma_width_t;
```

An enumeration defining the data transfer size for DMA operations on STM32 peripherals.

Membri:

Nome	Tipo	Descrizione
CA_DMA_WIDTH_8	enum constant	Configures the DMA to transfer data in 8-bit (byte) increments.
CA_DMA_WIDTH_16	enum constant	Configures the DMA to transfer data in 16-bit (halfword) increments.
CA_DMA_WIDTH_32	enum constant	Configures the DMA to transfer data in 32-bit (word) increments.

Note:
This enum must match the data alignment of the source and destination buffers. Using an incorrect width (e.g., 32-bit width for an 8-bit peripheral register) will result in data corruption or hardware bus errors.

Uso:
Used within DMA configuration structures to define the 'data width' parameter for both source and destination transfers. It ensures the DMA controller correctly increments its internal address pointers based on the peripheral's data register size.

Esempio:

```
ca_dma_config_t dma_cfg = { .src_width = CA_DMA_WIDTH_8, .dst_width =
    CA_DMA_WIDTH_8, .mode = DMA_MODE_NORMAL };
```

---

ca_dns_hdr_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:527:534

```
typedef struct {
u16 id;       /* transaction ID */
u16 flags;    /* QR|Opcode|AA|TC|RD|RA|Z|RCODE (big-endian) */
```

```
u16 qdcount;  /* question count */
u16 ancount;  /* answer count */
u16 nscount;  /* authority RR count */
u16 arcount;  /* additional RR count */
} __attribute__((packed)) ca_dns_hdr_t;
```

Represents the standard 12-byte DNS header structure used for parsing and constructing DNS network packets.

Membri:

Nome	Tipo	Descrizione
`id`	`u16`	Unique transaction identifier. Must be matched in the response to ensure the reply corresponds to the sent query.
`flags`	`u16`	Bitfield containing query/response type, opcode, and status codes. Must be handled in network byte order (big-endian).
`qdcount`	`u16`	Number of entries in the question section.
`ancount`	`u16`	Number of resource records in the answer section.
`nscount`	`u16`	Number of name server resource records in the authority section.
`arcount`	`u16`	Number of resource records in the additional section.

Note:
The struct is marked with ___attribute___((packed)) to prevent compiler padding, ensuring it maps exactly to the 12-byte wire format. Fields are in big-endian format; use htons() or ntohs() when accessing these fields on little-endian STM32 architectures.

Uso:
Used when manually crafting DNS packets or parsing incoming DNS responses from a socket buffer. Typically cast directly onto the start of a network buffer.

Esempio:

```
ca_dns_hdr_t dns_hdr;
dns_hdr.id = htons(0x1234);
dns_hdr.flags = htons(0x0100); // Standard query with recursion desired
dns_hdr.qdcount = htons(1);
dns_hdr.ancount = 0;
dns_hdr.nscount = 0;
dns_hdr.arcount = 0;
memcpy(buffer, &dns_hdr, sizeof(ca_dns_hdr_t));
```

`ca_dns_qtail_t`

Tipo: Struttura
File: `caos/net/inc/net_proto.h:537:540`

```
typedef struct {
u16 qtype;    /* DNS_TYPE_A = 1 */
u16 qclass;   /* DNS_CLASS_IN = 1 */
} __attribute__((packed)) ca_dns_qtail_t;
```

Represents the tail portion of a DNS query, specifying the resource record type and class.

Membri:

Nome	Tipo	Descrizione
qtype	u16	The type of DNS query (e.g., 1 for A record). Must be in network byte order.
qclass	u16	The class of the DNS query (e.g., 1 for IN/Internet). Must be in network byte order.

Note:
This struct is packed to ensure it maps directly to the wire format of a DNS packet. It does not contain pointers, so no dynamic memory allocation is required. The user is responsible for ensuring endianness conversion (e.g., using htons) before transmission.

Uso:
Used when constructing manual DNS query packets or parsing incoming DNS query responses to identify the requested resource type and class.

Esempio:

```
ca_dns_qtail_t query_tail;
query_tail.qtype = htons(1); // DNS_TYPE_A
query_tail.qclass = htons(1); // DNS_CLASS_IN
// Append query_tail to the DNS packet buffer before sending
```

---

ca_dns_response_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:501:505

```
typedef struct {
u16     id;     /* transaction ID (matches query) */
u8      rcode; /* DNS_RCODE_* */
ipv4_t ip;     /* resolved IPv4 (first A record); zero if not found */
} ca_dns_response_t;
```

A structure representing the result of a DNS resolution request, containing the transaction ID, status code, and resolved IP address.

Membri:

Nome	Tipo	Descrizione
id	u16	The transaction ID used to match the response with the original DNS query. Must match the ID sent in the request.
rcode	u8	The DNS response code (DNS_RCODE_*). Indicates success (0) or specific error types like NXDOMAIN or Server Failure.
ip	ca_ipv4_t	The resolved IPv4 address extracted from the first A record. Set to 0.0.0.0 if the resolution failed or no record was found.

Note:
This structure is typically populated by the caOS network stack upon completion of a DNS lookup. The memory is usually managed by the stack or provided by the caller as a buffer; it does not require manual heap allocation by the user.

Uso:
Used as an output parameter in DNS resolution APIs to retrieve the resolved IP address after a query has been processed by the network stack.

Esempio:

```c
ca_dns_response_t dns_res;
if (ca_dns_resolve("example.com", &dns_res) == CA_OK) {
    if (dns_res.rcode == DNS_RCODE_NO_ERROR) {
        printf("Resolved IP: %d.%d.%d.%d\n",
               dns_res.ip.addr[0], dns_res.ip.addr[1],
               dns_res.ip.addr[2], dns_res.ip.addr[3]);
    }
}
```

---

ca_dns_rr_hdr_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:543:548

```c
typedef struct {
u16 type;     /* record type */
u16 class_;   /* record class */
u32 ttl;      /* seconds to cache */
u16 rdlength; /* RDATA length in bytes; RDATA follows immediately */
} __attribute__((packed)) ca_dns_rr_hdr_t;
```

Represents the fixed-length header of a DNS Resource Record (RR) used when parsing or constructing DNS responses.

Membri:

Nome	Tipo	Descrizione
type	u16	The type of the resource record (e.g., A, AAAA, CNAME). Must be in network byte order.
class_	u16	The class of the resource record (usually 1 for IN-/Internet). Must be in network byte order.
ttl	u32	Time-to-live value in seconds, indicating how long the record can be cached. Must be in network byte order.
rdlength	u16	The length of the following RDATA field in bytes. Must be in network byte order.

Note:
This struct is packed to match the exact binary layout of DNS packets on the wire. It does not include the variable-length name field that precedes it in a real DNS packet. Fields are typically in big-endian (network) byte order, so use ntohs/ntohl when accessing them on little-endian STM32 hardware.

Uso:
Used when manually parsing a DNS response buffer or constructing a custom DNS packet. It is typically cast onto a pointer offset within a raw network buffer after skipping the variable-length domain name field.

Esempio:

```c
ca_dns_rr_hdr_t *rr_hdr = (ca_dns_rr_hdr_t *)(buffer + offset);
u16 type = ntohs(rr_hdr->type);
u32 ttl = ntohl(rr_hdr->ttl);
if (type == 1) { /* Handle A record */ }
```

---

ca_emergency_fn_t

Tipo: Callback
File: caos/inc/scheduler.h:142:142

```
typedef void (*ca_emergency_fn_t)(u32 task_idx, u32 emerg_param)
```

A function pointer type used to define a callback triggered during critical system emergency events.

Membri:

Nome	Tipo	Descrizione
task_idx	u32	The unique index of the task that was running when the emergency occurred. Used to identify the context of the failure.
emerg_param	u32	An error code or status parameter providing specific details about the nature of the emergency.

Note:
This callback is executed in a high-priority, restricted context. It must be kept extremely short, must not block, and should avoid calling complex OS services. It is typically registered during system initialization.

Uso:
Use this type when you need to define a custom handler for system-level emergencies, such as stack overflows or hardware faults, to perform emergency logging or safe state transitions.

Esempio:

```
void my_emergency_handler(u32 task_idx, u32 emerg_param) {
    /* Log the error to a non-volatile memory or toggle a safety LED */
    GPIO_Set(LED_RED_PIN);
}

/* Registering the handler */
ca_emergency_fn_t my_handler = my_emergency_handler;
```

---

ca_eth_cfg_t

Tipo: Struttura
File: caos/drivers/inc/eth.h:70:78

```
typedef struct {
u8                  phy_addr;    /* MDIO PHY address 0-31 */
bool                rmii;        /* true = RMII, false = MII */
mac_t               mac;         /* MAC address */
ca_eth_link_cb_t    link_cb;     /* task ctx: link UP/DOWN; NULL =
    ignore */
ca_eth_rx_cb_t      rx_cb;       /* ISR ctx: RX frame available; NULL =
    polling */
ca_eth_tx_done_cb_t tx_done_cb;  /* ISR ctx: TX complete; NULL = ignore
    */
ca_eth_error_cb_t   error_cb;    /* ISR ctx: DMA error; NULL = ignore */
} ca_eth_cfg_t;
```

Configuration structure used to initialize the Ethernet peripheral driver in caOS.

Membri:

Nome	Tipo	Descrizione
phy_addr	u8	The MDIO address of the external PHY chip. Valid range is 0-31. Incorrect values will prevent the driver from communicating with the PHY.
rmii	bool	Interface mode selection. Set true for RMII (Reduced Media Independent Interface) or false for MII. Must match the hardware PCB design.
mac	ca_mac_t	The 6-byte hardware MAC address assigned to the interface.
link_cb	ca_eth_link_cb_t	Callback function triggered when the link status changes. Executed in task context. Set to NULL if not needed.
rx_cb	ca_eth_rx_cb_t	Callback function triggered when a new frame is received. Executed in ISR context. If NULL, the driver assumes polling mode.
tx_done_cb	ca_eth_tx_done_cb_t	Callback function triggered after a frame transmission completes. Executed in ISR context. Set to NULL if not needed.
error_cb	ca_eth_error_cb_t	Callback function triggered on DMA or hardware errors. Executed in ISR context. Set to NULL if not needed.

Note:
The structure is typically passed by value or pointer to the driver initialization function. Ensure all callback functions are lightweight as they may execute within an ISR context. The user is responsible for the memory allocation of this struct, usually as a static or global variable.

Uso:
Use this structure to define the hardware interface parameters and event handlers before calling the Ethernet driver initialization routine.

Esempio:

```
ca_eth_cfg_t eth_config = { .phy_addr = 0, .rmii = true, .mac = {0x00, 0x80, 0
    xE1, 0x00, 0x00, 0x01}, .link_cb = my_link_handler, .rx_cb = my_rx_handler,
    .tx_done_cb = NULL, .error_cb = my_err_handler }; ca_eth_init(&eth_config);
```

---

ca_eth_error_cb_t

Tipo: Callback
File: caos/drivers/inc/eth.h:60:60

```
typedef void (*ca_eth_error_cb_t)(u32 flags)
```

A callback function pointer type triggered by the Ethernet driver when a hardware or protocol error occurs.

Membri:

Nome	Tipo	Descrizione
flags	u32	A bitmask representing the specific error conditions encountered (e.g., buffer overflow, link loss, or DMA error). Values are defined by the driver's error bitmask constants.

Note:

The callback is executed within the context of the Ethernet interrupt service routine (ISR) or a high-priority system task. It must be kept extremely short and non-blocking. Do not perform heavy processing or call blocking RTOS primitives inside this function. The user is responsible for registering this callback via the driver's configuration structure during initialization.

Uso:
Used to implement custom error handling or logging when the Ethernet peripheral encounters a fault. Assign a function pointer of this type to the error_cb field in the Ethernet configuration struct before calling the driver initialization function.

Esempio:

```
void my_eth_error_handler(u32 flags) {
    if (flags & ETH_ERR_DMA_MASK) {
        // Log DMA failure
    }
}

// During system setup:
eth_config_t config = {
    .error_cb = my_eth_error_handler
};
ca_eth_init(&config);
```

---

ca_eth_link_cb_t

Tipo: Callback
File: caos/drivers/inc/eth.h:48:48

```
typedef void (*ca_eth_link_cb_t)(bool up)
```

A callback function type triggered by the Ethernet driver whenever the physical link status changes.

Membri:

Nome	Tipo	Descrizione
up	bool	The new state of the Ethernet link. 'true' indicates the cable is connected and the link is active; 'false' indicates the link is down.

Note:
This callback is executed within the context of the Ethernet driver's interrupt service routine or a high-priority system task. Keep the implementation extremely short; do not perform blocking operations, heavy calculations, or memory allocation inside this function. The user is responsible for registering this callback via the driver's configuration structure during system initialization.

Uso:
Use this callback to monitor network connectivity in real-time. It is typically used to trigger application-level logic, such as restarting a DHCP client, notifying the TCP/IP stack to re-initialize, or updating an LED status indicator on the board.

Esempio:

```
void my_link_status_handler(bool up) {
    if (up) {
        printf("Ethernet link is UP!\n");
    } else {
        printf("Ethernet link is DOWN!\n");
    }
```

```
}

// Configuration during system setup
ca_eth_config_t eth_cfg = {
    .link_cb = my_link_status_handler
};
ca_eth_init(&eth_cfg);
```

---

ca_eth_rx_cb_t

Tipo: Callback
File: caos/drivers/inc/eth.h:52:52

```
typedef void (*ca_eth_rx_cb_t)(void)
```

A function pointer type used as a callback to notify the application when a new Ethernet frame has been received.

Membri:

Nome	Tipo	Descrizione
ca_eth_rx_cb_t	void (*)(void)	A pointer to a function that takes no arguments and returns nothing. This function is executed by the Ethernet driver's interrupt service routine or task context upon packet arrival.

Note:
This callback is executed in a high-priority context (often an ISR). Keep the implementation extremely short; do not perform blocking operations, heavy calculations, or long-running loops inside this function. If you need to process data, use the callback to signal a task (e.g., via a semaphore or queue) instead of processing the packet directly.

Uso:
Use this type when configuring the Ethernet driver to register a custom handler. It is typically passed to the driver initialization or configuration function to allow the application to react to incoming network traffic.

Esempio:

```
void my_network_handler(void) { /* Signal a task to process the packet */
    osSemaphoreRelease(eth_data_sem); } int main(void) { ca_eth_config_t config;
     config.rx_callback = my_network_handler; ca_eth_init(&config); }
```

---

ca_eth_tx_done_cb_t

Tipo: Callback
File: caos/drivers/inc/eth.h:56:56

```
typedef void (*ca_eth_tx_done_cb_t)(void)
```

A callback function pointer type triggered by the Ethernet driver when a packet transmission is successfully completed.

Membri:

Nome	Tipo	Descrizione
void	void	The callback takes no arguments and returns no value.

Note:
This callback is executed within the context of the Ethernet interrupt service routine (ISR) or a high-priority deferred task. It must be kept extremely short to avoid blocking the network stack. Do not perform blocking operations or heavy processing inside this function.

Uso:
Used to notify the application layer that a previously sent buffer is now free to be reused or deallocated. It is typically registered during the Ethernet driver initialization or configuration phase.

Esempio:

```
void my_tx_complete_handler(void) {
    // Signal a task that the buffer is free
    osSemaphoreRelease(tx_buffer_ready_sem);
}

// Registering the callback
ca_eth_config_t config = {
    .tx_done_cb = my_tx_complete_handler
};
ca_eth_init(&config);
```

---

ca_event_group_t

Tipo: Struttura
File: `caos/inc/event.h:71:76`

```
typedef struct {
volatile u32 bits;                      /**< 32 bit flags */
ca_wait_queue_t wait_queue;                 /**< Tasks waiting */
ca_spinlock_irq_t lock;                     /**< Concurrent access
    protection */
ca_event_waiter_meta_t waiters[MAX_TASK];    /**< Metadata for task
    index */
} ca_event_group_t;
```

A synchronization primitive used to manage and signal multiple event flags across different tasks.

Membri:

Nome	Tipo	Descrizione
`bits`	`volatile u32`	A bitmask where each bit represents a specific event state. Set bits indicate the event has occurred.
`wait_queue`	`ca_wait_queue_t`	Internal queue tracking tasks currently blocked waiting for specific bits to be set.
`lock`	`ca_spinlock_irq_t`	Spinlock used to ensure atomic access to the event group structure during concurrent operations.
`waiters`	`ca_event_waiter_meta_t[MAX_TASK]`	Array of metadata for each task waiting on this group, indexed by task ID.

Note:
The structure must be initialized before use. It is typically allocated statically in global memory or dynamically by the system. Ownership is managed by the kernel once passed to event API functions. Do not modify members directly; always use the provided ca_event_* API functions to ensure thread safety.

Uso:

Use this type when you need to synchronize multiple tasks based on one or more conditions. It is passed to functions like ca_event_wait() to block a task until specific bits are set, or ca_event_set() to notify waiting tasks.

Esempio:

```
ca_event_group_t my_event_group;

void init_system(void) {
    ca_event_init(&my_event_group);
}

void task_a(void *p) {
    // Wait for bit 0 or bit 1 to be set
    ca_event_wait(&my_event_group, 0x03, CA_EVENT_WAIT_ANY, CA_TIMEOUT_FOREVER);
}

void task_b(void *p) {
    // Signal that bit 0 has occurred
    ca_event_set(&my_event_group, 0x01);
}
```

---

ca_event_waiter_meta_t

Tipo: Struttura
File: caos/inc/event.h:60:65

```
typedef struct {
u32 wait_bits;        /**< Bit mask to wait for */
u8  wait_mode;        /**< CA_EVENT_WAIT_ANY or CA_EVENT_WAIT_ALL */
u8  auto_clear;       /**< If true, clear bits after match */
volatile u32 result; /**< Matched bits, set by wakeup_waiters; 0 = not
    signaled */
} ca_event_waiter_meta_t;
```

A configuration structure used to define the criteria and storage for a task waiting on an event group.

Membri:

Nome	Tipo	Descrizione
wait_bits	u32	A bitmask representing the specific events the task is interested in. Each bit corresponds to a flag in the event group.
wait_mode	u8	Determines logic: CA_EVENT_WAIT_ANY (wakes if any bit matches) or CA_EVENT_WAIT_ALL (wakes only if all bits match). Invalid values may cause undefined behavior.
auto_clear	u8	If set to 1, the matched bits are automatically cleared from the event group upon successful wake-up. If 0, bits remain set.
result	volatile u32	Output field populated by the kernel when the task is unblocked. Contains the actual bits that triggered the wake-up. 0 indicates no signal.

Note:

This structure is typically allocated on the stack of the waiting task. The 'result' field is volatile because it is modified by the kernel's scheduler/event handler context. Ensure the structure remains in scope until the task is unblocked.

Uso:
Used as a parameter in event waiting functions to specify the blocking condition. It acts as a bridge between the task's requirements and the kernel's event notification system.

Esempio:

```
ca_event_waiter_meta_t waiter = { .wait_bits = 0x03, .wait_mode =
    CA_EVENT_WAIT_ALL, .auto_clear = 1, .result = 0 };

if (ca_event_wait(my_event_group, &waiter, CA_TIMEOUT_FOREVER) == CA_OK) {
    if (waiter.result & 0x01) {
        /* Handle event bit 0 */
    }
}
```

---

ca_exti_cb_t

Tipo: Callback
File: caos/drivers/inc/exti.h:36:36

```
typedef void (*ca_exti_cb_t)(void)
```

A function pointer type used to define the callback routine executed when an external interrupt (EXTI) occurs.

Membri:

Nome	Tipo	Descrizione
void	void	The callback function takes no arguments and returns no value. It must be a standard C function or a static function within your driver/module.

Note:
The callback is executed within the context of the EXTI Interrupt Service Routine (ISR). Therefore, it must be kept extremely short and efficient. Do not perform blocking operations, heavy calculations, or use RTOS primitives that could block the system inside this callback.

Uso:
Used when registering an interrupt handler for a specific GPIO pin via the caOS EXTI driver. You assign a function pointer of this type to the configuration structure before calling the registration function.

Esempio:

```
static void my_button_handler(void) { /* Toggle an LED or set a flag */ } void
    init_exti(void) { ca_exti_config_t config = { .pin = GPIO_PIN_0, .callback =
     my_button_handler }; ca_exti_init(&config); }
```

---

ca_exti_edge_t

Tipo: Enumerazione
File: caos/drivers/inc/exti.h:29:33

```
typedef enum {
EXTI_EDGE_RISING  = 0,
EXTI_EDGE_FALLING = 1,
EXTI_EDGE_BOTH    = 2,
} ca_exti_edge_t;
```

Defines the signal transition type that triggers an external interrupt (EXTI) on an STM32 GPIO pin.

Membri:

Nome	Tipo	Descrizione
`CA_EXTI_EDGE_RISING`	`enum constant`	Interrupt triggers when the signal goes from Low to High (0 to 1).
`CA_EXTI_EDGE_FALLING`	`enum constant`	Interrupt triggers when the signal goes from High to Low (1 to 0).
`CA_EXTI_EDGE_BOTH`	`enum constant`	Interrupt triggers on both rising and falling edges.

Note:
This enum is used to configure the hardware trigger sensitivity of the EXTI controller. It does not allocate memory as it is a simple integer-based enumeration. Ensure the selected edge matches the physical signal characteristics of your connected sensor or button to avoid missed interrupts or false triggers.

Uso:
Used as a parameter in EXTI configuration functions to specify which signal edge should generate an interrupt request (IRQ) to the CPU.

Esempio:

```
ca_exti_edge_t edge_config = CA_EXTI_EDGE_FALLING;

// Example usage in a hypothetical driver configuration function
// Assuming a driver function exists to set the edge sensitivity
ca_exti_set_edge(CA_GPIO_PIN_0, edge_config);
```

`ca_fat_event_cb_t`

Tipo: Callback
File: `caos/drivers/inc/fat_service.h:39:39`

```
typedef void (*ca_fat_event_cb_t)(ca_fat_event_t ev, const char *what)
```

A callback function pointer type used to handle asynchronous file system events in the caOS FAT service.

Membri:

Nome	Tipo	Descrizione
`ev`	`ca_fat_event_t`	The specific event type that occurred (e.g., file creation, deletion, or error). Must be a valid member of the ca_fat_event_t enum.
`what`	`const char *`	A string pointer representing the file path or resource name associated with the event. Must be a null-terminated string.

Note:
The callback is executed within the context of the FAT service task. It must be non-blocking and should not perform heavy computations or call blocking RTOS primitives to avoid starving

the file system driver. The pointer 'what' is only guaranteed to be valid during the execution of the callback.

Uso:
Used to register an event listener with the FAT service. You assign a function matching this signature to the service configuration to monitor file system activity or handle errors in real-time.

Esempio:

```c
void my_fat_handler(ca_fat_event_t ev, const char *what) {
    if (ev == CA_FAT_EV_FILE_CREATED) {
        printf("New file detected: %s\n", what);
    }
}

// Usage in configuration
ca_fat_config_t config = {
    .event_cb = my_fat_handler
};
```

---

ca_fat_event_t

Tipo: Enumerazione
File: caos/drivers/inc/fat_service.h:33:37

```c
typedef enum {
CA_FAT_EV_MOUNTED = 0,    /* volume just mounted
    */
CA_FAT_EV_UNMOUNTING,     /* volume about to be unmounted: close files
    */
CA_FAT_EV_DESTRUCTIVE     /* fdisk/mkfs about to rewrite the card
    */
} ca_fat_event_t;
```

An enumeration representing lifecycle events of a FAT filesystem volume in caOS.

Membri:

Nome	Tipo	Descrizione
CA_FAT_EV_MOUNTED	enum constant	Triggered immediately after a filesystem volume is successfully mounted. Use this to initialize application-level file handles or logs.
CA_FAT_EV_UNMOUNTING	enum constant	Triggered before the volume is unmounted. You must close all open file handles immediately to prevent data corruption.
CA_FAT_EV_DESTRUCTIVE	enum constant	Triggered before a format or partition operation. All data on the volume will be lost; ensure no critical files are open.

Note:
This enum is typically passed as an argument to a callback function registered with the FAT service. The application does not allocate this; it is provided by the OS kernel as a notification of state changes.

Uso:
Use this type in your FAT event callback function to react to hardware changes (e.g., SD card insertion/removal) or administrative commands (e.g., formatting).

Esempio:

```c
void my_fat_callback(ca_fat_event_t event) {
    switch(event) {
        case CA_FAT_EV_MOUNTED:
            // Initialize file system tasks
            break;
        case CA_FAT_EV_UNMOUNTING:
            // Close all open files
            break;
        case CA_FAT_EV_DESTRUCTIVE:
            // Stop all file operations
            break;
    }
}
```

---

ca_fat_read_cb_t

Tipo: Callback
File: caos/drivers/inc/fat_service.h:97:97

```c
typedef bool (*ca_fat_read_cb_t)(const u8 *data, u32 len, void *user)
```

A callback function type used to process data chunks read from a file in the FAT filesystem.

Membri:

Nome	Tipo	Descrizione
data	const u8 *	Pointer to the buffer containing the data chunk read from the file. Do not modify this memory.
len	u32	The number of bytes available in the data buffer.
user	void *	User-defined context pointer passed through the FAT read function, useful for maintaining state.

Note:
The callback is invoked by the filesystem driver during read operations. It must return true to continue reading or false to abort the operation. The memory pointed to by 'data' is only valid for the duration of the callback execution.

Uso:
Used when reading files via ca_fat_read_enc to process file content in chunks without loading the entire file into memory.

Esempio:

```c
static bool my_read_handler(const u8 *data, u32 len, void *user) {
    /* Process the chunk of data here */
    ca_printf("Read %u bytes\n", len);
    return true; /* Continue reading */
}

void process_file(void) {
    /* Assuming file is already opened or handled by path */
    /* ca_fat_read_enc(path, offset, size, callback, user_ptr) */
    ca_fat_read_enc("test.txt", 0, 1024, my_read_handler, NULL);
}
```

---

ca_flash_key_block_hdr_t

Tipo: Struttura
File: caos/crypto/inc/keystore_service.h:48:55

```
typedef struct {
u32 size;
u8  IV[KSTORE_SVC_IV_SIZE];
u32 n_evolve;
u8  p1[KSTORE_SVC_P1_SIZE];
u16 n_key;
u8  gcm_nonce[KSTORE_SVC_NONCE_SIZE];
} ca_flash_key_block_hdr_t;    /* 4+16+4+16+2+12 = 54 byte */
```

A header structure used to manage the metadata and cryptographic context of a key block stored in non-volatile flash memory.

Membri:

Nome	Tipo	Descrizione
`size`	`u32`	Total size of the key block including the header and payload. Must match the actual stored data length to prevent buffer overflows.
`IV`	`u8[16]`	Initialization Vector used for AES-GCM decryption. Must be unique for every encryption operation to maintain security.
`n_evolve`	`u32`	Evolution counter used for key derivation or anti-rollback protection. Incremented during key updates.
`p1`	`u8[16]`	Padding or reserved field for future cryptographic parameters. Should be initialized to zero if unused.
`n_key`	`u16`	Identifier or index of the key stored within this block. Used to retrieve specific keys from the keystore.
`gcm_nonce`	`u8[12]`	GCM mode nonce. Must be unique per key block to ensure the integrity and confidentiality of the encrypted data.

Note:
This structure is typically mapped directly onto flash memory. It is not dynamically allocated by the RTOS; it is usually declared as a static struct or part of a larger flash-mapped structure. Ensure the struct is packed if the compiler adds padding, as flash layouts must be byte-aligned to the hardware specification.

Uso:
Used by the Keystore Service to verify and decrypt key blocks retrieved from flash. It is passed as a pointer to internal keystore functions when reading or writing encrypted key material.

Esempio:

```
ca_flash_key_block_hdr_t my_key_hdr = { .size = 128, .n_key = 0x01 };
// Initialize IV and nonce with secure random values before writing to flash
memcpy(my_key_hdr.IV, random_iv, KSTORE_SVC_IV_SIZE);
memcpy(my_key_hdr.gcm_nonce, random_nonce, KSTORE_SVC_NONCE_SIZE);
```

`ca_flash_key_entry_t`

Tipo: Struttura
File: `caos/crypto/inc/keystore_service.h:39:45`

```
typedef struct {
u16 key_id;
```

```
u8  label[KSTORE_SVC_LABEL_SIZE];
u8  key[KSTORE_SVC_KEY_SIZE];
u32 start;      /* KSTORE_DATE_PACK validity start (0 = no limit) */
u32 stop;       /* KSTORE_DATE_PACK validity stop  (0 = no limit) */
} ca_flash_key_entry_t;    /* 2+6+32+4+4 = 48 byte */
```

A structure representing a single cryptographic key entry stored in the non-volatile flash memory.

Membri:

Nome	Tipo	Descrizione
`key_id`	`u16`	Unique identifier for the key. Must be unique within the keystore to avoid collisions.
`label`	`u8[KSTORE_SVC_LABEL_SIZE]`	Human-readable identifier or alias for the key. Must be null-terminated if treated as a string.
`key`	`u8[KSTORE_SVC_KEY_SIZE]`	The raw cryptographic key material. Ensure this buffer is populated with secure, high-entropy data.
`start`	`u32`	Validity start timestamp in KSTORE_DATE_PACK format. Set to 0 to indicate no start restriction.
`stop`	`u32`	Validity end timestamp in KSTORE_DATE_PACK format. Set to 0 to indicate no expiration.

Note:
This structure is typically used for direct flash mapping. Ensure the struct is packed if the compiler alignment settings differ from the expected 48-byte layout. The application is responsible for allocating this memory, usually on the stack or as a static global before passing it to the keystore service functions.

Uso:
Use this type when interacting with the keystore service to add, update, or retrieve cryptographic keys from the device's secure flash storage.

Esempio:

```
ca_flash_key_entry_t my_key = { .key_id = 0x01, .label = "AES_KEY_01", .key = {0
    x01, 0x02, 0x03}, .start = 0, .stop = 0 };
```

`ca_fmac_filter_t`

Tipo: Struttura
File: `caos/drivers/inc/fmac.h:54:61`

```
typedef struct {
const i16 *b;       /* feed-forward coefficients b[0..nb-1] */
u32        nb;
const i16 *a;       /* feedback a[1..na] (a[0] is not passed), NULL for a
    FIR */
u32        na;
u32        gain;    /* output x 2^gain, 0..7 */
bool       clip;    /* saturate the output instead of wrapping */
} ca_fmac_filter_t;
```

Configuration structure for the hardware Filter-MAC (FMAC) unit, used to define filter coefficients and processing behavior.

Membri:

Nome	Tipo	Descrizione
b	const i16 *	Pointer to the feed-forward coefficients array. Must be valid for the duration of the filter operation.
nb	u32	Number of feed-forward coefficients (length of array b).
a	const i16 *	Pointer to feedback coefficients array. Set to NULL for FIR filters; required for IIR filters.
na	u32	Number of feedback coefficients. Ignored if a is NULL.
gain	u32	Output scaling factor applied as x * 2^gain. Valid range is 0 to 7.
clip	bool	If true, saturates the output at the maximum/minimum value instead of allowing integer overflow/wrapping.

Note:
The structure is passed by value to the initialization function. The coefficient arrays (b and a) must reside in memory accessible by the FMAC peripheral (typically static or global memory) and must not be modified while the filter is running.

Uso:
Used to configure the FMAC hardware before processing data streams. Pass this struct to ca_fmac_init to set up the filter parameters.

Esempio:

```
static const i16 my_b_coeffs[] = {100, 200, 100};
ca_fmac_filter_t my_filter = {
    .b = my_b_coeffs,
    .nb = 3,
    .a = NULL,
    .na = 0,
    .gain = 1,
    .clip = true
};

// Initialize the FMAC hardware with the defined filter
ca_fmac_init(&my_filter);
```

---

ca_gpio_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:64:69

```
typedef enum {
CA_GPIO_MODE_INPUT = 0,
CA_GPIO_MODE_OUTPUT,
GPIO_MODE_AF,
CA_GPIO_MODE_ANALOG,
} ca_gpio_mode_t;
```

Defines the electrical operating mode for a GPIO pin (e.g., input, output, analog, or alternate function).

Membri:

Nome	Tipo	Descrizione
CA_GPIO_MODE_INPUT	enum value	Configures the pin as a digital input. Used to read external signals.
CA_GPIO_MODE_OUTPUT	enum value	Configures the pin as a digital output. Used to drive external components like LEDs.
GPIO_MODE_AF	enum value	Configures the pin for Alternate Function (e.g., UART, SPI, or PWM peripheral usage).
CA_GPIO_MODE_ANALOG	enum value	Configures the pin for analog mode. Required for ADC or DAC operations.

Note:
This enum is passed to the ca_gpio_configure function. Ensure the pin is initialized via ca_gpio_init_port before attempting to change its mode. Incorrect mode selection may cause electrical conflicts if the pin is connected to an active external signal.

Uso:
Use this type when configuring GPIO pins during system startup or peripheral setup. It is the primary argument for the mode parameter in the ca_gpio_configure function.

Esempio:

```c
#include "caos/drivers/inc/gpio_driver.h"

void setup_led(void) {
    /* Initialize the GPIO port first */
    ca_gpio_init_port(0);

    /* Configure pin 5 on port 0 as an output to drive an LED */
    ca_gpio_configure(0, 5, CA_GPIO_MODE_OUTPUT);

    /* Turn the LED on */
    ca_gpio_write(0, 5, 1);
}
```

---

ca_gpio_otype_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:74:77

```c
typedef enum {
CA_GPIO_OTYPE_PP = 0,   /*!< Push-pull */
CA_GPIO_OTYPE_OD,       /*!< Open-drain */
} ca_gpio_otype_t;
```

Defines the output configuration mode for a GPIO pin, determining how the pin drives the electrical signal.

Membri:

Nome	Tipo	Descrizione
CA_GPIO_OTYPE_PP	enum constant	Push-pull configuration. The pin actively drives both high (VCC) and low (GND). Use for standard digital outputs.
CA_GPIO_OTYPE_OD	enum constant	Open-drain configuration. The pin can only drive low (GND) or float (high impedance). Requires an external pull-up resistor to drive high.

Note:

This enum is typically passed as a member of a GPIO configuration structure. It does not require manual allocation as it is a simple enumeration type. Ensure the hardware circuit matches the selected mode, especially for Open-drain, which requires an external pull-up resistor to function correctly as a high-level output.

Uso:
Used during the initialization phase of a GPIO peripheral to configure the output driver type. It is passed to the GPIO configuration function to set the hardware registers of the STM32 GPIO port.

Esempio:

```
ca_gpio_config_t my_pin_config = {
    .pin = CA_GPIO_PIN_5,
    .mode = CA_GPIO_MODE_OUTPUT,
    .otype = CA_GPIO_OTYPE_PP,
    .speed = CA_GPIO_SPEED_HIGH
};
ca_gpio_init(GPIOA, &my_pin_config);
```

---

ca_gpio_pin_t

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:42:59`

```
typedef enum {
CA_GPIO_PIN_0 = 0,
CA_GPIO_PIN_1,
GPIO_PIN_2,
CA_GPIO_PIN_3,
GPIO_PIN_4,
CA_GPIO_PIN_5,
GPIO_PIN_6,
CA_GPIO_PIN_7,
GPIO_PIN_8,
CA_GPIO_PIN_9,
GPIO_PIN_10,
CA_GPIO_PIN_11,
GPIO_PIN_12,
CA_GPIO_PIN_13,
GPIO_PIN_14,
CA_GPIO_PIN_15,
} ca_gpio_pin_t;
```

An enumeration representing the 16 individual pins available on a single STM32 GPIO port.

Membri:

Nome	Tipo	Descrizione
`CA_GPIO_PIN_0 to CA_GPIO_PIN_15`	`enum constant`	Represents the specific pin index (0-15) on a GPIO port. Using an invalid value outside this range will result in undefined behavior in driver functions.

Note:
This enum is used to identify a specific pin within a port. Note that while some constants are prefixed with 'CA_', others are not; ensure you use the provided constants consistently. These values are typically passed as arguments to GPIO configuration and state-setting functions.

Uso:

Use this type when configuring pin modes (input/output/alternate function) or when reading/writing the digital state of a specific pin on a port.

Esempio:

```
ca_gpio_pin_t my_pin = CA_GPIO_PIN_5;

// Example usage in a hypothetical driver function
ca_gpio_set_mode(GPIOA, my_pin, CA_GPIO_MODE_OUTPUT);
ca_gpio_write(GPIOA, my_pin, CA_GPIO_STATE_HIGH);
```

---

ca_gpio_port_t

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:25:37`

```
typedef enum {
CA_GPIO_PORT_A = 0,
CA_GPIO_PORT_B,
GPIO_PORT_C,
CA_GPIO_PORT_D,
GPIO_PORT_E,
CA_GPIO_PORT_F,
GPIO_PORT_G,
CA_GPIO_PORT_H,
GPIO_PORT_I,
CA_GPIO_PORT_J,
GPIO_PORT_K,
} ca_gpio_port_t;
```

An enumeration representing the available physical GPIO ports on the STM32 microcontroller.

Membri:

Nome	Tipo	Descrizione
`CA_GPIO_PORT_A through CA_GPIO_PORT_K`	`enum constant`	Represents the specific hardware port GPIOA, GPIOB). Ensure the selected port e on your specific STM32 chip variant to avoic defined behavior.

Note:
This enum is used to abstract hardware-specific port identifiers. It is typically passed by value to driver functions. Note that some ports may not be physically bonded or available on smaller STM32 packages; verify your datasheet before use.

Uso:
Used as a parameter in GPIO configuration and control functions to specify which port the operation should target. It is the primary way to identify a port in the caOS GPIO driver API.

Esempio:

```
ca_gpio_port_t my_port = CA_GPIO_PORT_A;

// Example usage in a hypothetical driver function
ca_gpio_init(my_port, 5, CA_GPIO_MODE_OUTPUT);
```

---

ca_gpio_pull_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:92:96

```
typedef enum {
CA_GPIO_NOPULL = 0,
CA_GPIO_PULLUP,
GPIO_PULLDOWN,
} ca_gpio_pull_t;
```

An enumeration defining the internal resistor configuration for an STM32 GPIO pin.

Membri:

Nome	Tipo	Descrizione
CA_GPIO_NOPULL	enum constant	Disables both pull-up and pull-down resistors. The pin is in a high-impedance state.
CA_GPIO_PULLUP	enum constant	Connects an internal pull-up resistor to VDD. Used to keep the line high when no external device is driving it.
GPIO_PULLDOWN	enum constant	Connects an internal pull-down resistor to VSS. Used to keep the line low when no external device is driving it.

Note:
This enum is used to configure the electrical state of a GPIO pin during initialization. Ensure the chosen pull configuration matches your hardware schematic to avoid floating inputs or short circuits.

Uso:
Pass this value to the GPIO configuration structure (typically passed to a driver initialization function) to define the default state of a pin when it is not being actively driven by an external source.

Esempio:

```
ca_gpio_config_t my_pin_config = { .pin = 5, .mode = CA_GPIO_MODE_INPUT, .pull =
    CA_GPIO_PULLUP };
```

---

ca_gpio_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:82:87

```
typedef enum {
CA_GPIO_SPEED_LOW = 0,
CA_GPIO_SPEED_MED,
GPIO_SPEED_HIGH,
CA_GPIO_SPEED_VERY_HIGH,
} ca_gpio_speed_t;
```

An enumeration defining the output slew rate (speed) of an STM32 GPIO pin.

Membri:

Nome	Tipo	Descrizione
CA_GPIO_SPEED_LOW	enum constant	Lowest slew rate. Reduces electromagnetic interference (EMI) and power consumption. Use for low-frequency signals like status LEDs or buttons.
CA_GPIO_SPEED_MED	enum constant	Medium slew rate. A balance between signal integrity and power consumption.
GPIO_SPEED_HIGH	enum constant	High slew rate. Used for communication interfaces like SPI or UART where faster rise/fall times are required.
CA_GPIO_SPEED_VERY_HIGH	enum constant	Maximum slew rate. Use only for high-speed peripherals. Note: High speeds can cause signal ringing and increased noise.

Note:
This enum is used to configure the GPIO_OSPEEDR register in the STM32 hardware. Choosing a speed higher than necessary can increase noise on the PCB; always select the lowest speed that meets your signal timing requirements.

Uso:
Used within the GPIO configuration structure when initializing a pin via the driver's setup functions to define how fast the pin can toggle.

Esempio:

```
ca_gpio_cfg_t my_pin_cfg = {
    .mode = CA_GPIO_MODE_OUTPUT,
    .speed = CA_GPIO_SPEED_MED,
    .pull = CA_GPIO_PULL_NONE
};
ca_gpio_init(GPIOA, GPIO_PIN_5, &my_pin_cfg);
```

---

ca_hash_algo_t

Tipo: Enumerazione
File: caos/drivers/inc/hash.h:26:29

```
typedef enum {
HASH_ALGO_SHA1   = 0,
HASH_ALGO_SHA256 = 1,
} ca_hash_algo_t;
```

An enumeration defining the supported cryptographic hashing algorithms available in the caOS hardware abstraction layer.

Membri:

Nome	Tipo	Descrizione
CA_HASH_ALGO_SHA1	enum constant	Selects the SHA-1 hashing algorithm. Note: SHA-1 is considered cryptographically insecure for modern security applications.
CA_HASH_ALGO_SHA256	enum constant	Selects the SHA-256 hashing algorithm. This is the recommended standard for most data integrity and security tasks.

Note:
This enum is used to configure the hardware hashing engine. Ensure the selected algorithm is supported by the specific STM32 hardware variant being used, as some older chips may not support SHA-256.

Uso:
Pass this type as an argument to the initialization or configuration functions of the caOS HASH driver to specify which algorithm the hardware peripheral should execute.

Esempio:

```
ca_hash_algo_t selected_algo = CA_HASH_ALGO_SHA256;

// Configure the hash peripheral with the chosen algorithm
ca_hash_init(selected_algo);

// Proceed to process data buffers
ca_hash_update(data_buffer, buffer_size);
```

---

ca_hash_ctx_t

Tipo: Struttura
File: `caos/drivers/inc/hash.h:45:52`

```
typedef struct {
ca_hash_algo_t algo;
bool started;               /* an update has begun buffering
    */
bool error;                 /* allocation failed -> final() fails
    */
u32  len;                   /* bytes buffered so far
    */
u32  cap;                   /* current buf capacity
    */
u8  *buf;                   /* heap buffer (ca_memory_allocate)
    */
} ca_hash_ctx_t;
```

Context structure used to manage incremental hashing operations (e.g., SHA256) in caOS.

Membri:

Nome	Tipo	Descrizione
`algo`	`ca_hash_algo_t`	The specific hashing algorithm selected for the operation.
`started`	`bool`	Flag indicating if the hashing process has been initialized and is currently buffering data.
`error`	`bool`	Error flag set if internal heap allocation fails; if true, subsequent calls to final() will fail.
`len`	`u32`	Number of bytes currently stored in the internal buffer.
`cap`	`u32`	Total capacity of the allocated buffer.
`buf`	`u8 *`	Pointer to the heap-allocated memory buffer used to store data chunks before hashing.

Note:
The context must be initialized via ca_hash_ctx_init before use. The buffer is dynamically allocated on the heap using ca_memory_allocate; therefore, the user must call ca_hash_ctx_free to prevent memory leaks once the hashing operation is complete.

Uso:
Used for hashing large data streams that do not fit into memory at once. The typical pattern is: initialize context, call update repeatedly with data chunks, and finally call final to retrieve the digest.

Esempio:

```
ca_hash_ctx_t ctx;
u8 data_chunk[] = {0x01, 0x02, 0x03};
u8 digest[32];

/* Initialize the hashing context */
ca_hash_ctx_init(&ctx, CA_HASH_SHA256);

/* Feed data into the context */
ca_hash_ctx_update(&ctx, data_chunk, sizeof(data_chunk));

/* Finalize the hash and store result in digest */
ca_hash_ctx_final(&ctx, digest);

/* Clean up allocated memory */
ca_hash_ctx_free(&ctx);
```

---

ca_hmac_sha256_ctx_t

Tipo: Struttura
File: caos/crypto/inc/kdf.h:36:39

```
typedef struct {
ca_sha256_ctx_t inner;
ca_sha256_ctx_t outer;      /* already keyed with K ^ opad */
} ca_hmac_sha256_ctx_t;
```

Context structure for performing HMAC-SHA256 operations, holding the internal state for the inner and outer hash calculations.

Membri:

Nome	Tipo	Descrizione
inner	ca_sha256_ctx_t	Context for the inner SHA256 hash calculation, initialized with the key XORed with the ipad.
outer	ca_sha256_ctx_t	Context for the outer SHA256 hash calculation, initialized with the key XORed with the opad.

Note:
This structure is used by the HMAC-SHA256 API. It is typically allocated on the stack by the caller. The user must initialize it using ca_hmac_sha256_init before passing it to update or final functions. It does not require explicit freeing as it contains no dynamic pointers.

Uso:
Use this structure when you need to compute an HMAC-SHA256 signature over a stream of data. It is passed as the first argument to ca_hmac_sha256_init, ca_hmac_sha256_update, and ca_hmac_sha256_final.

Esempio:

```
#include "caos/crypto/inc/kdf.h"

void compute_hmac(uint8_t *key, size_t key_len, uint8_t *data, size_t data_len)
    {
    ca_hmac_sha256_ctx_t ctx;
    uint8_t digest[32];

    /* Initialize the HMAC context with the provided key */
    ca_hmac_sha256_init(&ctx, key, key_len);

```

```
    /* Process the data stream */
    ca_hmac_sha256_update(&ctx, data, data_len);

    /* Finalize the HMAC and store the result in digest */
    ca_hmac_sha256_final(&ctx, digest);
}
```

---

ca_http_conn_t

Tipo: Struttura
File: caos/net/inc/http_service.h:134:138

```
typedef struct {
u8                  rx[HTTP_REQ_BUF_SIZE];
u8                  tx[HTTP_RESP_BUF_SIZE];
ca_http_response_t  resp;
} ca_http_conn_t;
```

Represents a single HTTP connection state, including buffers for incoming requests and outgoing responses.

Membri:

Nome	Tipo	Descrizione
rx	u8[HTTP_REQ_BUF_SIZE]	Buffer for incoming HTTP request data. Must be large enough to hold the full request header.
tx	u8[HTTP_RESP_BUF_SIZE]	Buffer for outgoing HTTP response data. Used by ca_http_resp_* functions to build the response.
resp	ca_http_response_t	Structure tracking the current response state (e.g., status code, headers, chunking state).

Note:
This structure is typically allocated by the application or the HTTP server task. It is passed to ca_http_serve_connection to process a specific client request. Ensure the buffers are not accessed by other tasks while the HTTP service is actively using the connection.

Uso:
Used when implementing a custom HTTP server or handling specific HTTP requests. It is passed as a pointer to ca_http_serve_connection to handle the lifecycle of a single HTTP transaction.

Esempio:

```
ca_http_conn_t my_conn;

void handle_client(void) {
    /* Initialize connection buffers to zero before use */
    ca_memzero(&my_conn, sizeof(ca_http_conn_t));

    /* Process the connection using the caOS HTTP service */
    /* Note: 'socket_fd' would be obtained from a TCP accept call */
    ca_http_serve_connection(socket_fd, &my_conn);
}
```

---

ca_http_handler_fn

Tipo: Callback
File: caos/net/inc/http_service.h:108:108

```
typedef void (*ca_http_handler_fn)(const ca_http_request_t *req,
```

A callback function type used to process incoming HTTP requests in the caOS web server.

Membri:

Nome	Tipo	Descrizione
`req`	`const ca_http_request_t *`	Pointer to the structure containing the HTTP request details (method, URI, headers, body). Must not be modified.

Note:
This callback is invoked by the HTTP service thread when a valid request is received. The implementation must be thread-safe and should return quickly to avoid blocking the HTTP service. You are responsible for using ca_http_resp_* functions to send the response back to the client.

Uso:
Used when implementing custom HTTP endpoints. You define a function matching this signature and register it with the HTTP service (if the service provides a registration mechanism) to handle specific URI paths.

Esempio:

```
void my_http_handler(const ca_http_request_t *req) {
    /* Check the request and send a response */
    ca_http_resp_begin(req, 200);
    ca_http_resp_puts(req, "Hello from caOS!");
    ca_http_resp_flush(req);
}
```

`ca_http_io_t`

Tipo: Struttura
File: `caos/net/inc/http_service.h:52:56`

```
typedef struct {
bool  (*send)(void *io, const u8 *data, u16 len);
i32   (*recv)(void *io, u8 *buf, u16 len, u32 timeout_ms);
void   *io;
} ca_http_io_t;
```

An abstraction layer (interface) used by the HTTP service to perform read/write operations on a generic I/O stream.

Membri:

Nome	Tipo	Descrizione
send	bool (*)(void *io, const u8 *data, u16 len)	Function pointer to send data. Returns true on success, false on failure. Must handle the provided length.
recv	i32 (*)(void *io, u8 *buf, u16 len, u32 timeout_ms)	Function pointer to receive data. Returns the number of bytes read, or a negative value on error/timeout.
io	void *	Opaque pointer to the underlying hardware or software context (e.g., a socket handle or UART instance) passed to the callbacks.

Note:
This struct is not managed by caOS; the user must allocate it (usually on the stack or as a static global) and populate the function pointers. The 'io' member acts as the 'this' pointer for the callbacks. Ensure the callbacks are thread-safe if the HTTP service is accessed by multiple tasks.

Uso:
Used when configuring or initiating an HTTP connection or service where the underlying transport is not fixed (e.g., switching between UART, TCP, or TLS). It allows the HTTP logic to remain agnostic of the physical transport layer.

Esempio:

```c
/* Example of defining a custom I/O interface for a hypothetical stream */

bool my_send(void *io, const u8 *data, u16 len) {
    /* Implementation using ca_uart_dma_send or similar */
    return true;
}

i32 my_recv(void *io, u8 *buf, u16 len, u32 timeout_ms) {
    /* Implementation using ca_uart_dma_recv or similar */
    return (i32)len;
}

void setup_http_io(void) {
    ca_http_io_t my_io_interface;
    my_io_interface.send = my_send;
    my_io_interface.recv = my_recv;
    my_io_interface.io = NULL; /* Pointer to specific hardware context */

    /* The interface is now ready to be passed to ca_http service functions */
}
```

---

ca_http_request_t

Tipo: Struttura
File: caos/net/inc/http_service.h:37:43

```c
typedef struct {
u8   method;                    /* HTTP_METHOD_* */
char uri[HTTP_URI_MAX];         /* path, es. "/status" */
```

```
char query[HTTP_QUERY_MAX];      /* query string dopo '?', es. "state=on" */
const u8 *body;                  /* puntatore nel rx buffer (POST body) */
u16  body_len;
} ca_http_request_t;
```

Represents an incoming HTTP request structure used by the caOS HTTP service to pass request details to handlers.

Membri:

Nome	Tipo	Descrizione
`method`	`u8`	The HTTP verb (e.g., GET, POST). Must be one of the HTTP_METHOD_* constants. Invalid values will cause the handler to fail to identify the request type.
`uri`	`char[]`	The target path of the request (e.g., '/api/data'). Must be null-terminated. Exceeding HTTP_URI_MAX will cause buffer overflow or truncation.
`query`	`char[]`	The query string parameters following the '?' character. Must be null-terminated. If empty, should be an empty string.
`body`	`const u8 *`	A pointer to the raw request payload located in the system RX buffer. Do not modify this memory as it is managed by the network stack.
`body_len`	`u16`	The length of the data pointed to by body in bytes. Must match the actual payload size to prevent reading out-of-bounds memory.

Note:
This struct is typically populated by the caOS HTTP service layer before calling a registered callback. The memory for the 'body' pointer is owned by the network stack and is only valid for the duration of the callback execution. Do not store this pointer for asynchronous processing.

Uso:
Used in HTTP callback functions registered with the caOS HTTP service. When a client sends a request, the service fills this struct and passes it to your handler to determine the requested resource and process any provided data.

Esempio:

```
void my_http_handler(ca_http_request_t *req) {
    if (req->method == HTTP_METHOD_GET) {
        if (strcmp(req->uri, "/status") == 0) {
            // Handle status request
        }
    } else if (req->method == HTTP_METHOD_POST) {
        // Process req->body of length req->body_len
    }
}
```

`ca_http_response_t`

Tipo: Struttura
File: `caos/net/inc/http_service.h:46:62`

```c
typedef struct {
u8  *buf;           /* output buffer (provided by the service) */
u16  size;          /* buffer size */
u16  len;           /* bytes written so far */
u16  cl_pos;        /* offset of the Content-Length placeholder in the
   buf (0 = not used) */
u16  hdr_end;       /* offset where the body starts (after \r\n\r\n) */
bool head_only;     /* true if HEAD method: skip body */
/*        chunked transfer (RFC 7230  4 .1)

* Set by ca_http_resp_begin_chunked(). In this mode the body is NOT
* accumulated: every flush leaves the buffer as a self-contained chunk
   on
* the wire, so the response is not bounded by `size`. Content-Length is
* absent by definition -- which is the whole point: it cannot be patched
* afterwards if the body was never held in memory. */
bool chunked;       /* true = emit chunks instead of one buffered body
   */
u8   conn;          /* TCP handle used to flush chunks (0 = none) */
bool failed;        /* a flush failed: stop writing, close the
   connection */
} ca_http_response_t;
```

A structure representing the state and buffer management for an outgoing HTTP response in the caOS network stack.

Membri:

Nome	Tipo	Descrizione
`buf`	`u8*`	Pointer to the memory buffer where the HTTP response headers and body are stored. Managed by the service.
`size`	`u16`	Total capacity of the buffer in bytes. Must not be exceeded to prevent memory corruption.
`len`	`u16`	Current number of bytes written into the buffer.
`cl_pos`	`u16`	Offset index for the Content-Length header value. If 0, the header is not being tracked.
`hdr_end`	`u16`	Offset index marking the end of the HTTP header section (after the double CRLF).
`head_only`	`bool`	If true, the service will omit the response body, typically used for HEAD requests.
`chunked`	`bool`	If true, enables chunked transfer encoding, allowing streaming of data without a pre-defined Content-Length.
`conn`	`u8`	The TCP connection handle associated with this response. 0 indicates no active connection.
`failed`	`bool`	Flag indicating a transmission error occurred. If true, the response process should be aborted.

Note:
This structure is typically allocated by the caOS HTTP service layer. Users should not manually modify the internal offsets (cl_pos, hdr_end) unless using specific service helper functions. When chunked mode is enabled, the buffer is flushed incrementally, meaning the total response size is not limited by the buffer size.

Uso:

Used by HTTP handler callbacks to construct and send responses to clients. It is passed as a parameter to functions that write headers or body content to the network.

Esempio:

```
ca_http_response_t resp;
resp.buf = my_buffer;
resp.size = 512;
resp.len = 0;
resp.chunked = false;
resp.head_only = false;
resp.failed = false;
// Proceed to populate headers and body using service-provided functions
```

---

ca_http_route_t

Tipo: Struttura
File: caos/net/inc/http_service.h:78:82

```
typedef struct {
const char         *uri;      /* es. "/status"     confronto esatto */
u8                  methods;  /* bitmask HTTP_METHOD_* accettati */
ca_http_handler_fn handler;
} ca_http_route_t;
```

Defines a mapping between a specific URI path and a callback function to handle HTTP requests.

Membri:

Nome	Tipo	Descrizione
uri	const char *	The exact string path to match (e.g., '/api/data'). Must be a null-terminated string.
methods	u8	A bitmask of allowed HTTP methods (e.g., HTTP_METHOD_GET | HTTP_METHOD_POST). If set to 0, the route will not trigger.
handler	ca_http_handler_fn	The function pointer to be executed when the URI and method match. Must match the signature defined by ca_http_handler_fn.

Note:
The struct is typically defined as a static constant array to save RAM. The HTTP service iterates through these routes to find a match; ensure the URI strings are unique to avoid shadowing.

Uso:
Used to register endpoints with the caOS HTTP server. You pass an array of these structs to the HTTP service initialization or registration function to define the API surface of your device.

Esempio:

```
static void my_handler(ca_http_req_t *req) { /* Handle request */ } static const
    ca_http_route_t my_routes[] = { { .uri = "/status", .methods =
   HTTP_METHOD_GET, .handler = my_handler } };
```

---

ca_i2c_config_t

Tipo: Struttura
File: caos/drivers/inc/i2c.h:28:32

```
typedef struct {
u8              i2c_num;    /* 1, 2, 3 */
ca_i2c_speed_t  speed;
u16             irq_req;    /* I2C_EN_IRQ to enable EV IRQ+NVIC, 0 =
   polling only */
} ca_i2c_config_t;
```

Configuration structure used to initialize an I2C peripheral instance in caOS.

Membri:

Nome	Tipo	Descrizione
i2c_num	u8	The hardware peripheral index (e.g., 1, 2, or 3). Must match the physical STM32 I2C peripheral mapping.
speed	ca_i2c_speed_t	The desired bus clock frequency (e.g., standard mode 100kHz or fast mode 400kHz). Ensure the value is supported by the hardware clock configuration.
irq_req	u16	Interrupt request flags. Set to I2C_EN_IRQ to enable event-driven interrupts and NVIC configuration, or 0 to force blocking polling mode.

Note:
This structure is typically passed by value to the initialization function. It does not require dynamic allocation; it is usually declared on the stack or as a static constant. The user is responsible for ensuring the i2c_num corresponds to a valid, non-conflicting peripheral on the specific STM32 target.

Uso:
Use this structure as an argument when calling the driver initialization function to configure the I2C bus parameters before performing any read or write operations.

Esempio:

```
ca_i2c_config_t i2c_cfg = { .i2c_num = 1, .speed = I2C_SPEED_400K, .irq_req =
   I2C_EN_IRQ }; ca_i2c_init(&i2c_cfg);
```

---

ca_i2c_slave_ctx_t

Tipo: Struttura
File: caos/drivers/inc/i2c.h:38:47

```
typedef struct {
u8                  addr;
u8                  rx_buf[64];
u8                  rx_idx;
u8                  tx_buf[64];
u8                  tx_len;
u8                  tx_idx;
bool                is_slave;
ca_i2c_slave_rx_cb  rx_cb;
} ca_i2c_slave_ctx_t;
```

A configuration and state structure used to manage an I2C slave peripheral instance in caOS.

Membri:

Nome	Tipo	Descrizione
`addr`	`u8`	The 7-bit I2C slave address. Must be unique on the bus to avoid collisions.
`rx_buf`	`u8[64]`	Internal buffer for incoming data. Fixed size of 64 bytes; do not overflow.
`rx_idx`	`u8`	Current write index for the receive buffer. Managed by the driver.
`tx_buf`	`u8[64]`	Buffer containing data to be sent to the master. Fixed size of 64 bytes.
`tx_len`	`u8`	Total number of bytes currently available in tx_buf to be transmitted.
`tx_idx`	`u8`	Current read index for the transmit buffer. Managed by the driver.
`is_slave`	`bool`	Flag to identify the operating mode. Must be set to true for slave operation.
`rx_cb`	`ca_i2c_slave_rx_cb`	Callback function pointer triggered when data is received. Can be NULL if not needed.

Note:
The structure must be zero-initialized before use. The user is responsible for allocating this struct, typically as a static global variable to ensure it persists for the lifetime of the driver. The driver manages the indices (rx_idx, tx_idx) internally during I2C interrupts.

Uso:
Used to initialize an I2C peripheral in slave mode. Pass a pointer to this struct to the driver initialization function to register the slave address and the callback for data processing.

Esempio:

```
static ca_i2c_slave_ctx_t my_i2c_slave = {0};

void my_rx_handler(u8 *data, u8 len) {
    // Process received data
}

void setup_slave(void) {
    my_i2c_slave.addr = 0x42;
    my_i2c_slave.is_slave = true;
    my_i2c_slave.rx_cb = my_rx_handler;
    ca_i2c_init(&my_i2c_slave);
}
```

`ca_i2c_slave_rx_cb`

Tipo: Callback
File: `caos/drivers/inc/i2c.h:35:35`

```
typedef void (*ca_i2c_slave_rx_cb)(u8 num, const u8 *buf, u8 len)
```

A callback function pointer type triggered by the I2C driver when the MCU receives data as a slave device.

Membri:

Nome	Tipo	Descrizione
num	u8	The index or ID of the I2C peripheral instance that received the data. Must match the hardware peripheral index.
buf	const u8 *	Pointer to the buffer containing the received data. This memory is managed by the driver and is read-only.
len	u8	The number of bytes received in the current transaction. Valid range is 0 to the maximum buffer size configured for the I2C slave.

Note:
This callback is executed in the context of the I2C interrupt service routine. Keep the logic inside this function extremely brief; do not perform blocking operations or heavy processing. The buffer pointer is only guaranteed to be valid for the duration of the callback execution.

Uso:
Used to register a custom handler with the I2C slave driver. You assign a function of this type to the driver's configuration structure before initializing the I2C peripheral to process incoming data packets asynchronously.

Esempio:

```
void my_i2c_rx_handler(u8 num, const u8 *buf, u8 len) {
    if (len > 0) {
        process_data(buf[0]);
    }
}

// During initialization
ca_i2c_config_t config = {
    .slave_rx_cb = my_i2c_rx_handler
};
ca_i2c_init(0, &config);
```

---

ca_i2c_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/i2c.h:23:26

```
typedef enum __attribute__ ((packed)) {
I2C_SPEED_STANDARD = 0,   /* 100 kHz */
I2C_SPEED_FAST     = 1,   /* 400 kHz */
} ca_i2c_speed_t;
```

An enumeration defining the clock frequency modes for I2C communication.

Membri:

Nome	Tipo	Descrizione
CA_I2C_SPEED_STANDARD	enum constant	Sets the I2C bus speed to 100 kHz. Use this for standard-mode devices or when long wires are used.
CA_I2C_SPEED_FAST	enum constant	Sets the I2C bus speed to 400 kHz. Use this for high-speed peripherals to improve data throughput.

Note:

This enum is packed to ensure a 1-byte memory footprint. It is typically passed by value to driver configuration structures. Ensure the hardware peripheral and the connected slave device both support the selected speed, otherwise, communication will fail.

Uso:
Used during the initialization phase of an I2C peripheral to configure the bus timing parameters before the bus is enabled.

Esempio:

```
ca_i2c_config_t config;
config.speed = CA_I2C_SPEED_FAST;
ca_i2c_init(I2C1, &config);
```

---

ca_icmp_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:92:94

```
typedef struct {
bool echo_reply; /* true = respond to ICMP echo request (ping) */
} ca_icmp_cfg_t;
```

Configuration structure for the ICMP (Internet Control Message Protocol) stack behavior.

Membri:

Nome	Tipo	Descrizione
echo_reply	bool	Enables or disables the device's response to ICMP Echo Request packets (ping). Set to true to allow the device to respond to pings, false to ignore them.

Note:
This structure is typically passed as part of a larger network configuration object during the initialization phase of the network stack. It does not require dynamic memory allocation and is usually defined as a static constant or local variable before being passed to the network configuration API.

Uso:
Use this struct when configuring the network stack parameters to define whether the device should be discoverable via ping requests. It is passed to the network stack initialization function to set the ICMP protocol behavior.

Esempio:

```
ca_icmp_cfg_t icmp_config = { .echo_reply = true };

// Pass the configuration to the network stack initialization
ca_net_init_cfg_t net_cfg = {
    .icmp = &icmp_config,
    // ... other configuration fields
};
ca_net_init(&net_cfg);
```

---

ca_icmp_echo_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:126:132

```
typedef struct {
u8      type;         /* 8 = echo request, 0 = echo reply */
u8      code;         /* 0 */
u16     checksum;     /* big-endian */
u16     id;           /* identifier big-endian */
u16     seq;          /* sequence number big-endian */
} __attribute__((packed)) ca_icmp_echo_t;
```

Represents the header structure of an ICMP Echo message (ping) used for network connectivity testing.

Membri:

Nome	Tipo	Descrizione
type	u8	ICMP message type. Use 8 for Echo Request and 0 for Echo Reply. Incorrect values will cause the packet to be ignored by the stack.
code	u8	ICMP code field. Must be 0 for Echo messages.
checksum	u16	16-bit one's complement of the one's complement sum of the ICMP message. Must be calculated in big-endian format.
id	u16	Identifier to match requests with replies. Must be provided in big-endian format.
seq	u16	Sequence number to track packets. Must be provided in big-endian format.

Note:
The struct is marked with ___attribute___((packed)) to ensure no padding bytes are added by the compiler, matching the exact wire format of the ICMP protocol. Fields requiring multi-byte values (u16) must be converted to network byte order (big-endian) before transmission.

Uso:
Used when manually constructing ICMP packets for network diagnostics or implementing custom ping utilities within the caOS network stack.

Esempio:

```
ca_icmp_echo_t ping_pkt;
ping_pkt.type = 8;
ping_pkt.code = 0;
ping_pkt.id = htons(0x1234);
ping_pkt.seq = htons(1);
ping_pkt.checksum = 0; // Calculate checksum here
// Proceed to send packet via network interface
```

---

ca_ip4_frame_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:104:115

```
typedef struct {
u8      ver_ihl;      /* version[7:4]=4 | IHL[3:0] in 32-bit words */
u8      dscp_ecn;     /* DSCP[7:2] | ECN[1:0] */
u16     total_len;    /* total length incl. header big-endian */
u16     id;           /* identification big-endian */
u16     flags_frag;   /* flags[15:13] | fragment offset[12:0] big-endian
    */
u8      ttl;          /* time to live */
```

```
u8     proto;        /* IP_PROTO_* */
u16    cksum;        /* header checksum big-endian */
ca_ipv4_t src;          /* source IPv4 */
ca_ipv4_t dst;          /* destination IPv4 */
} __attribute__((packed)) ca_ip4_frame_t;
```

Represents the standard IPv4 header structure used for parsing and constructing network packets in the caOS networking stack.

Membri:

Nome	Tipo	Descrizione
`ver_ihl`	`u8`	Version (upper 4 bits, must be 4) and Internet Header Length (lower 4 bits, number of 32-bit words). Incorrect values will cause the packet to be dropped by the network stack.
`dscp_ecn`	`u8`	Differentiated Services Code Point and Explicit Congestion Notification bits. Usually set to 0 for standard traffic.
`total_len`	`u16`	Total length of the IP packet including header and data in bytes. Must be in big-endian format.
`id`	`u16`	Identification field for packet fragmentation. Must be in big-endian format.
`flags_frag`	`u16`	Flags (3 bits) and fragment offset (13 bits). Must be in big-endian format.
`ttl`	`u8`	Time to Live: decremented by each router. If it reaches 0, the packet is discarded.
`proto`	`u8`	Protocol identifier (e.g., 6 for TCP, 17 for UDP). Defines the payload type.
`cksum`	`u16`	Header checksum. Must be calculated correctly or the packet will be rejected by the receiver.
`src`	`ca_ipv4_t`	Source IPv4 address.
`dst`	`ca_ipv4_t`	Destination IPv4 address.

Note:
This struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, matching the exact wire format of an IPv4 header. Fields requiring multi-byte values (u16) must be converted to network byte order (big-endian) before transmission.

Uso:
Used when manually crafting raw IP packets or parsing incoming network buffers. It is typically cast onto a pointer of a received network buffer to access header fields directly.

Esempio:

```
ca_ip4_frame_t *ip_hdr = (ca_ip4_frame_t *)buffer_ptr;
if (ip_hdr->ver_ihl >> 4 == 4) {
    ca_ipv4_t source = ip_hdr->src;
    // Process packet header fields
}
```

`ca_iperf_result_t`

Tipo: Struttura
File: `caos/net/inc/iperf_service.h:11:15`

```
typedef struct {
u32 bytes_total;
u32 duration_ms;
u32 bps;            /* bits per second */
} ca_iperf_result_t;
```

A structure used to store the performance metrics collected after an iPerf network test session.

Membri:

Nome	Tipo	Descrizione
bytes_total	u32	The total number of bytes successfully transferred during the test. Must be non-negative.
duration_ms	u32	The total duration of the test in milliseconds. Used to calculate throughput.
bps	u32	The calculated throughput in bits per second. Derived from bytes_total and duration_ms.

Note:
This structure is typically populated by the caOS iPerf service upon completion of a measurement. It is a plain data structure (POD) and does not require dynamic memory allocation or explicit cleanup. The values are usually read-only for the application layer once the test finishes.

Uso:
Use this type to retrieve and display network performance statistics after calling the iPerf service functions. It allows the application to log or report the bandwidth efficiency of the current network configuration.

Esempio:

```
ca_iperf_result_t result;

/* Assuming iperf_get_last_result is the API to retrieve the data */
if (iperf_get_last_result(&result) == CA_OK) {
    printf("Test complete: %u bytes in %u ms\n", result.bytes_total, result.
    duration_ms);
    printf("Throughput: %u bps\n", result.bps);
}
```

---

ca_ipv4_t

Tipo: union
File: caos/net/inc/net_cfg.h:38:41

```
typedef union {
u32 addr;   /* comparison: a.addr == b.addr  |  assignment: dst = src */
u8  v[4];   /* octet access: ip.v[0] .. ip.v[3]                        */
} ca_ipv4_t;
```

A union representing an IPv4 address, allowing access either as a single 32-bit integer or as an array of four 8-bit octets.

Membri:

Nome	Tipo	Descrizione
addr	u32	The IPv4 address stored as a 32-bit unsigned integer. Useful for direct comparisons or copying the entire address at once.
v	u8[4]	The IPv4 address stored as an array of four bytes (octets). Useful for accessing specific segments of the IP address (e.g., v[0] for the first octet).

Note:
This is a union, meaning both members share the same memory location. Modifying one member will change the value of the other. It is typically allocated on the stack or as part of a larger network configuration structure. No dynamic memory allocation is required.

Uso:
Use this type whenever you need to store or manipulate an IPv4 address in network-related configurations or packet headers. It is designed to provide flexibility between treating the address as a single numerical value or as individual bytes.

Esempio:

```
ca_ipv4_t my_ip; my_ip.v[0] = 192; my_ip.v[1] = 168; my_ip.v[2] = 1; my_ip.v[3] = 10; if (my_ip.addr == 0x0A01A8C0) { /* Logic for specific IP */ }
```

---

ca_job_type

Tipo: Enumerazione
File: caos/inc/scheduler.h:53:60

```
typedef enum ca_job_type_t{
CA_JOB_STD,
JOB_SAFE,
#if __FPU_PRESENT
JOB_FLOAT_POINT,
CA_JOB_SAFE_FLOAT_POINT,
#endif
}ca_job_type;
```

An enumeration defining the execution context and hardware requirements for a task (job) in the caOS scheduler.

Membri:

Nome	Tipo	Descrizione
CA_JOB_STD	enum constant	Standard task execution. Uses integer registers only. Most efficient for general logic.
JOB_SAFE	enum constant	Task with stack overflow protection enabled. Use this for critical tasks where memory corruption must be detected.
JOB_FLOAT_POINT	enum constant	Task that performs floating-point calculations. Requires the FPU context to be saved/restored during context switches.
CA_JOB_SAFE_FLOAT_POINT	enum constant	Combines both stack protection and FPU context support. Use for critical tasks performing math.

Note:
The availability of floating-point types depends on the ___FPU_PRESENT macro defined in the CMSIS device header. If you select a float-enabled type on a device without an FPU, the

behavior is undefined. Always ensure the stack size is sufficient when using 'SAFE' variants, as they may add overhead for monitoring.

Uso:
This type is passed as an argument during task creation (e.g., when calling the scheduler's task spawn functions) to inform the kernel how to configure the CPU registers and memory protection unit for that specific thread.

Esempio:

```
ca_job_type my_task_type = JOB_FLOAT_POINT;

// Example of passing the type to a task creation function
ca_task_create(my_task_function, "TaskName", 256, NULL, 1, my_task_type);
```

---

ca_jpeg_cfg_t

Tipo: Struttura
File: caos/drivers/inc/jpeg.h:52:57

```
typedef struct {
u16            width;
u16            height;
ca_jpeg_css_t  css;
u8             quality;      /* 1..100, encoding only */
} ca_jpeg_cfg_t;
```

Configuration structure for JPEG image processing, defining dimensions, color space, and compression quality.

Membri:

Nome	Tipo	Descrizione
width	u16	Image width in pixels. Must be a multiple of 8 or 16 depending on the color space.
height	u16	Image height in pixels. Must be a multiple of 8 or 16 depending on the color space.
css	ca_jpeg_css_t	Chroma Subsampling format (e.g., 4:2:0, 4:2:2, 4:4:4). Incorrect values will cause encoding/decoding errors.
quality	u8	Compression quality factor, ranging from 1 (lowest quality, highest compression) to 100 (highest quality, lowest compression). Used only during encoding.

Note:
This struct is passed by value or pointer to ca_jpeg functions. It does not require dynamic allocation; it is typically declared on the stack by the user before calling initialization or processing functions.

Uso:
Used to configure the JPEG hardware peripheral before starting an encode or decode operation. Pass this struct to ca_jpeg_init to set up the hardware context.

Esempio:

```
#include "caos/drivers/inc/jpeg.h"

void setup_jpeg_task(void) {
```

```
    ca_jpeg_cfg_t config;

    /* Initialize configuration for a 640x480 image */
    config.width = 640;
    config.height = 480;
    config.css = 0; /* Assuming 0 maps to a valid ca_jpeg_css_t enum value */
    config.quality = 85;

    /* Apply configuration to the JPEG peripheral */
    ca_jpeg_init(&config);
}
```

---

ca_jpeg_css_t

Tipo: Enumerazione
File: caos/drivers/inc/jpeg.h:45:50

```
typedef enum {
CA_JPEG_GRAY = 0,
CA_JPEG_444,
CA_JPEG_422,
CA_JPEG_420
} ca_jpeg_css_t;
```

Defines the Chroma Subsampling (CSS) format used for JPEG image encoding and decoding.

Membri:

Nome	Tipo	Descrizione
CA_JPEG_GRAY	enum value	Grayscale (no chroma subsampling). Uses only the luminance channel.
CA_JPEG_444	enum value	4:4:4 subsampling. No chroma reduction; highest quality, largest file size.
CA_JPEG_422	enum value	4:2:2 subsampling. Horizontal chroma reduction by factor of 2.
CA_JPEG_420	enum value	4:2:0 subsampling. Horizontal and vertical chroma reduction by factor of 2. Most common for standard JPEG compression.

Note:
This enum is passed to JPEG driver functions to configure the color space conversion logic. Ensure the selected mode matches the source image buffer format and the desired compression ratio.

Uso:
Used as a parameter in ca_jpeg_encode or ca_jpeg_decode functions to specify how the MCU (Minimum Coded Unit) data is interpreted or generated.

Esempio:

```
#include "caos/drivers/inc/jpeg.h"

void process_image(void) {
    /* Define the subsampling format for the JPEG encoder */
    ca_jpeg_css_t format = CA_JPEG_420;

    /* Initialize the JPEG hardware peripheral */
    ca_jpeg_init();

```

```
    /*
     * Perform encoding operation.
     * Note: ca_jpeg_encode is the hypothetical function used to process
     * the image buffer using the specified format.
     */
    // ca_jpeg_encode(input_buffer, output_buffer, format);
}
```

---

ca_jpeg_info_t

Tipo: Struttura
File: caos/drivers/inc/jpeg.h:59:65

```
typedef struct {
u16            width;
u16            height;
ca_jpeg_css_t  css;
u32            mcus;          /* MCUs of the image */
u32            mcu_bytes;     /* total MCU data, mcus x bytes per MCU */
} ca_jpeg_info_t;
```

Structure containing metadata about a JPEG image, such as dimensions and MCU (Minimum Coded Unit) layout.

Membri:

Nome	Tipo	Descrizione
width	u16	Image width in pixels.
height	u16	Image height in pixels.
css	ca_jpeg_css_t	Chroma Subsampling format (e.g., 4:2:0, 4:2:2).
mcus	u32	Total number of MCUs in the image.
mcu_bytes	u32	Total size of MCU data in bytes (calculated as mcus * bytes_per_mcu).

Note:
This structure is typically populated by the ca_jpeg_geometry function. It is used by the application to allocate appropriate buffers before calling decoding or encoding functions. The memory for this struct is usually provided by the caller on the stack or as a static variable.

Uso:
Use this struct to retrieve image properties from a JPEG stream or file header using ca_jpeg_geometry. The resulting values are essential for calculating buffer sizes required for ca_jpeg_decode or ca_jpeg_encode operations.

Esempio:

```
#include "caos/drivers/inc/jpeg.h"

void process_jpeg_info(void *jpeg_data, u32 size) {
    ca_jpeg_info_t info;

    /* Retrieve geometry information from the raw JPEG data */
    if (ca_jpeg_geometry(jpeg_data, size, &info) == 0) {
        ca_printf("Image dimensions: %u x %u\n", info.width, info.height);
        ca_printf("Total MCUs: %u, Total bytes: %u\n", info.mcus, info.mcu_bytes
    );

        /* Proceed to decode using the retrieved info */
        /* ca_jpeg_decode(jpeg_data, size, ...); */
    }
```

```
}
```

---

ca_keys_store_access_mode_t

Tipo: Enumerazione
File: caos/crypto/inc/keys_store.h:42:47

```
typedef enum {
CA_KEYS_STORE_NO_ACCESS = 0,        /* No access allowed (region disabled
    ) */
CA_KEYS_STORE_READ_ONLY = 1,        /* Read-only allowed */
CA_KEYS_STORE_READ_WRITE = 2,       /* Read and write allowed */
CA_KEYS_STORE_EXEC_ONLY = 3         /* Execute-only allowed (rarely used)
     */
} ca_keys_store_access_mode_t;
```

Defines the permission levels for accessing a specific key storage region in the caOS crypto subsystem.

Membri:

Nome	Tipo	Descrizione
CA_KEYS_STORE_NO_ACCESS	enum value	Region is disabled; any attempt to access keys will fail.
CA_KEYS_STORE_READ_ONLY	enum value	Only read operations are permitted on the keys in this region.
CA_KEYS_STORE_READ_WRITE	enum value	Both read and write operations are permitted.
CA_KEYS_STORE_EXEC_ONLY	enum value	Only execution (e.g., cryptographic operations) is permitted; rarely used.

Note:
This enum is used to configure the hardware or software protection level of key storage regions. It is typically passed to ca_keys_store_set_access_mode to update the security policy of a specific key slot. Ensure the mode is set correctly before performing cryptographic operations to avoid access violations.

Uso:
Use this type when managing key storage security policies via the ca_keys_store_* API family, specifically when initializing or dynamically updating the access permissions of a key storage region.

Esempio:

```
#include "caos/crypto/inc/keys_store.h"

void update_key_security(void) {
    /* Define the desired access mode for a key storage region */
    ca_keys_store_access_mode_t new_mode = CA_KEYS_STORE_READ_ONLY;

    /* Apply the access mode to the key store */
    /* Note: 'key_id' is a placeholder for the specific key index being managed
    */
    ca_keys_store_set_access_mode(key_id, new_mode);
}
```

---

ca_l2_frame_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:75:79

```
typedef struct {
ca_mac_t  dst;          /* destination MAC */
ca_mac_t  src;          /* source MAC */
u16    ethertype;   /* EtherType big-endian: ETH_P_IP / ETH_P_ARP /
   ETH_P_VLAN */
} __attribute__((packed)) ca_l2_frame_t;
```

Represents the standard Ethernet Layer 2 header structure used for packet transmission and reception.

Membri:

Nome	Tipo	Descrizione
dst	ca_mac_t	The 6-byte destination MAC address. Must be a valid unicast, multicast, or broadcast address.
src	ca_mac_t	The 6-byte source MAC address of the local network interface.
ethertype	u16	The protocol identifier (e.g., 0x0800 for IPv4). Must be provided in Big-Endian format (network byte order).

Note:
The struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, matching the exact wire format of an Ethernet frame. Users are responsible for ensuring the ethertype is converted to network byte order using appropriate macros if the CPU is Little-Endian.

Uso:
Used when manually constructing raw Ethernet frames for network drivers or packet injection. It is typically cast to the start of a buffer before passing the pointer to the low-level transmission function.

Esempio:

```
ca_l2_frame_t frame;
memcpy(frame.dst.addr, target_mac, 6);
memcpy(frame.src.addr, local_mac, 6);
frame.ethertype = htons(ETH_P_IP);

/* Proceed to copy payload data immediately after the header */
u8 *packet_ptr = (u8*)&frame;
ca_net_send(packet_ptr, sizeof(ca_l2_frame_t) + payload_len);
```

---

ca_l2_result_t

Tipo: Enumerazione
File: caos/net/inc/net_proto.h:181:186

```
typedef enum {
CA_L2_ACCEPT_UNICAST   = 0,
CA_L2_ACCEPT_BROADCAST = 1,
CA_L2_ACCEPT_MULTICAST = 2,
CA_L2_DROP             = 3,
} ca_l2_result_t;
```

An enumeration used by Layer 2 network callbacks to instruct the stack on how to handle an incoming data frame.

Membri:

Nome	Tipo	Descrizione
`CA_L2_ACCEPT_UNICAST`	`enum constant`	Accepts the frame because it is addressed specifically to this device. Processing continues.
`CA_L2_ACCEPT_BROADCAST`	`enum constant`	Accepts the frame as it is intended for all devices on the network segment.
`CA_L2_ACCEPT_MULTICAST`	`enum constant`	Accepts the frame because the device is subscribed to the specific multicast group.
`CA_L2_DROP`	`enum constant`	Rejects the frame. The stack will discard the packet immediately, saving memory and processing time.

Note:
This enum is returned by user-defined filter callbacks registered within the caOS network stack. The stack relies on this return value to decide whether to allocate buffer resources for the incoming packet. Returning an invalid value may lead to undefined behavior in the packet processing pipeline.

Uso:
Use this type as the return value for your L2 frame filtering functions. It is typically used when implementing custom MAC address filtering or protocol-specific packet inspection to prevent unnecessary processing of irrelevant traffic.

Esempio:

```
ca_l2_result_t my_frame_filter(const uint8_t *mac_addr) {
    if (is_my_mac(mac_addr)) {
        return CA_L2_ACCEPT_UNICAST;
    } else if (is_broadcast(mac_addr)) {
        return CA_L2_ACCEPT_BROADCAST;
    }
    return CA_L2_DROP;
}
```

`ca_l2_vlan_frame_t`

Tipo: Struttura
File: `caos/net/inc/net_proto.h:82:88`

```
typedef struct {
ca_mac_t  dst;          /* destination MAC */
ca_mac_t  src;          /* source MAC */
u16     tpid;         /* 0x8100 big-endian */
u16     tci;          /* PCP[15:13] | DEI[12] | VID[11:0] big-endian */
u16     ethertype;    /* inner EtherType big-endian */
} __attribute__((packed)) ca_l2_vlan_frame_t;
```

Represents an IEEE 802.1Q tagged Ethernet frame header used for VLAN-aware network communication.

Membri:

Nome	Tipo	Descrizione
dst	ca_mac_t	The 6-byte destination MAC address. Must be a valid unicast, multicast, or broadcast address.
src	ca_mac_t	The 6-byte source MAC address of the sending interface.
tpid	u16	Tag Protocol Identifier. Must be set to 0x8100 (in big-endian) to indicate a VLAN-tagged frame.
tci	u16	Tag Control Information. Contains 3 bits for Priority (PCP), 1 bit for Drop Eligible Indicator (DEI), and 12 bits for the VLAN ID (VID). Must be provided in big-endian format.
ethertype	u16	The protocol type of the encapsulated payload (e.g., 0x0800 for IPv4). Must be in big-endian.

Note:
This struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, matching the exact wire format of an Ethernet frame. Always use network byte order (big-endian) for the 16-bit fields to ensure compatibility with network hardware.

Uso:
Used when constructing or parsing raw Ethernet frames in the caOS network stack. It is typically cast over a buffer received from the NIC driver or used to populate a buffer before transmission.

Esempio:

```
ca_l2_vlan_frame_t frame;
memset(&frame, 0, sizeof(ca_l2_vlan_frame_t));
frame.tpid = htons(0x8100);
frame.tci = htons(0x000A); // VLAN ID 10
frame.ethertype = htons(0x0800); // IPv4
memcpy(frame.dst.addr, dest_mac, 6);
memcpy(frame.src.addr, my_mac, 6);
```

---

ca_lptim_cb_t

Tipo: Callback
File: caos/drivers/inc/lptim.h:43:43

```
typedef void (*ca_lptim_cb_t)(void)
```

A function pointer type used to define a callback function triggered by the Low Power Timer (LPTIM) interrupt.

Membri:

Nome	Tipo	Descrizione
void	void	The callback function takes no arguments and returns no value.

Note:
The callback is executed within the context of the LPTIM interrupt service routine (ISR). Keep the implementation extremely short and avoid blocking operations or heavy processing. Ensure the function is defined with a void return type and no parameters to match the signature.

Uso:
Use this type when configuring the LPTIM driver to specify a custom action that should occur upon a timer event (e.g., overflow or compare match). It is typically passed to the LPTIM initialization or configuration function provided by the caOS driver API.

Esempio:

```
void my_lptim_handler(void) {
    /* Toggle an LED or set a flag for the main loop */
    HAL_GPIO_TogglePin(GPIOA, CA_GPIO_PIN_5);
}

/* Registering the callback */
ca_lptim_cb_t my_callback = my_lptim_handler;
ca_lptim_set_callback(my_callback);
```

---

ca_lptim_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/lptim.h:45:48

```
typedef enum {
LPTIM_MODE_PERIODIC = 0,
LPTIM_MODE_ONESHOT,
} ca_lptim_mode_t;
```

Defines the operational behavior of the Low Power Timer (LPTIM) peripheral regarding signal generation.

Membri:

Nome	Tipo	Descrizione
CA_LPTIM_MODE_PERIODIC	enum constant	The timer automatically reloads and restarts after reaching the compare value, creating a continuous pulse train.
CA_LPTIM_MODE_ONESHOT	enum constant	The timer stops automatically after the first match event occurs; requires manual restart to trigger again.

Note:
This enum is used during the LPTIM configuration phase. It determines whether the hardware peripheral will generate a continuous signal or a single event. Ensure the mode matches your application's timing requirements to avoid unexpected interrupt flooding in periodic mode.

Uso:
Passed as a parameter to the LPTIM initialization or configuration functions to set the hardware operating mode before starting the timer.

Esempio:

```
ca_lptim_config_t config;
config.mode = CA_LPTIM_MODE_ONESHOT;
config.prescaler = LPTIM_PRESCALER_DIV1;
ca_lptim_init(LPTIM1, &config);
```

---

ca_lpuart_rx_cb_t

Tipo: Callback
File: caos/drivers/inc/lpuart.h:42:42

```
typedef void (*ca_lpuart_rx_cb_t)(u8 byte)
```

A function pointer type used as a callback to handle individual bytes received by the LPUART peripheral.

Membri:

Nome	Tipo	Descrizione
byte	u8	The 8-bit data byte received from the LPUART hardware buffer. Valid range is 0x00 to 0xFF.

Note:
This callback is executed within the LPUART Interrupt Service Routine (ISR) context. It must be kept extremely short and efficient to avoid blocking other system interrupts. Do not perform blocking operations, heavy calculations, or complex RTOS primitives (like long-duration mutex locks) inside this function.

Uso:
Used when configuring the LPUART driver to register a custom handler for incoming data. It is typically passed to the driver initialization or configuration function to enable asynchronous byte-by-byte processing.

Esempio:

```
void my_rx_handler(u8 byte) {
    if (byte == '\n') {
        // Signal a task that a full message has arrived
    }
}

// During driver setup:
ca_lpuart_config_t config = {
    .rx_cb = my_rx_handler,
    .baudrate = 115200
};
ca_lpuart_init(LPUART1, &config);
```

---

ca_mac_t

Tipo: union
File: caos/net/inc/net_cfg.h:44:50

```
typedef union {
struct {
u32 l;  // First 4 bytes of the MAC (0, 1, 2, 3)
u16 h; // Last 2 bytes of the MAC (4, 5)
} __attribute__((packed)) raw;
u8  v[6];      // For access to individual bytes
} ca_mac_t;
```

A union representing a 6-byte MAC address, allowing access either as an array of bytes or as split 32-bit and 16-bit integers.

Membri:

Nome	Tipo	Descrizione
raw	struct	Provides access to the MAC address split into a 32-bit integer (first 4 bytes) and a 16-bit integer (last 2 bytes). Useful for hardware register mapping.
v	u8[6]	Provides direct access to the 6 individual bytes of the MAC address. Use this for standard array-based iteration or network packet construction.

Note:
The union is packed to ensure no padding bytes are inserted by the compiler, maintaining a strict 6-byte footprint. It is typically allocated on the stack or as part of a configuration struct. The user is responsible for the byte order (endianness) when assigning values to the 'raw' struct members.

Uso:
Used in network configuration structures and Ethernet driver APIs to store or pass MAC addresses. Use the 'v' array for easy indexing (e.g., v[0] to v[5]) when parsing or printing MAC addresses.

Esempio:

```
ca_mac_t my_mac = {.v = {0x00, 0x80, 0xE1, 0x00, 0x00, 0x01}};

// Accessing via array
printf("MAC: %02X:%02X:%02X:%02X:%02X:%02X\n",
       my_mac.v[0], my_mac.v[1], my_mac.v[2],
       my_mac.v[3], my_mac.v[4], my_mac.v[5]);

// Accessing via raw struct
u32 first_part = my_mac.raw.l;
u16 last_part = my_mac.raw.h;
```

---

ca_mem_range

Tipo: Struttura
File: caos/inc/memory.h:171:175

```
typedef struct {
u32  addr;               /**< base address */
u32  size;               /**< size in BYTES */
char name[12];           /**< "RAM1".."RAMn" by ascending address, "FLASH
   " */
} ca_mem_range;
```

Defines a contiguous block of memory within the system, used by the kernel to manage memory regions.

Membri:

Nome	Tipo	Descrizione
addr	u32	The starting physical address of the memory block. Must be aligned according to hardware requirements.
size	u32	The total size of the memory block in bytes. Ensure this does not exceed the actual physical memory boundaries.
name	char[12]	A human-readable identifier for the memory region (e.g., 'RAM1', 'FLASH'). Limited to 11 characters plus the null terminator.

Note:
This structure is typically used in static configuration arrays. The memory it describes must be physically present and accessible by the CPU. The kernel does not allocate this struct; it is usually defined as a global constant in the board support package (BSP).

Uso:

Used during system initialization to inform the caOS memory manager about available memory segments. It is passed to kernel memory registration functions to define the heap or memory pools.

Esempio:

```
const ca_mem_range my_ram_region = { .addr = 0x20000000, .size = 0x20000, .name = "RAM1" };
```

---

ca_memory_check_t

Tipo: Struttura
File: caos/inc/memory.h:143:157

```
typedef struct {
u32  blocks;        /**< blocks walked, START and END included */
u32  busy;          /**< BUSY blocks */
u32  busy_bytes;    /**< payload of the BUSY blocks */
u32  free;          /**< FREE blocks */
u32  free_bytes;    /**< payload of the FREE blocks */
u32  largest_free;  /**< largest FREE payload: the biggest allocation that can succeed */
u32  unmerged;      /**< FREE blocks followed by another FREE one (missed merge) */
u32  avail;         /**< g_avail_mem as the allocator holds it */
u32  avail_expect;  /**< what the chain says it should be */
u32  bad_addr;      /**< first block that failed a check, 0 if none */
cstr bad_what;      /**< which check it failed, NULL if none */
bool chain_ok;      /**< every header valid, linked both ways, contiguous */
bool canary_ok;     /**< ca_memory_check_canary() */
} ca_memory_check_t;
```

A diagnostic structure used to report the health and fragmentation status of the caOS heap memory allocator.

Membri:

Nome	Tipo	Descrizione
`blocks`	`u32`	Total number of memory blocks traversed during the heap walk.
`busy`	`u32`	Number of blocks currently allocated to the application.
`busy_bytes`	`u32`	Total bytes currently in use by allocated blocks.
`free`	`u32`	Number of blocks currently available for allocation.
`free_bytes`	`u32`	Total bytes available across all free blocks.
`largest_free`	`u32`	The size of the largest contiguous free block; represents the maximum possible single allocation.
`unmerged`	`u32`	Count of adjacent free blocks that should have been merged; indicates potential heap fragmentation issues.
`avail`	`u32`	The total available memory reported by the allocator's internal counter.
`avail_expect`	`u32`	The total available memory calculated by summing the free blocks in the chain; should match 'avail'.
`bad_addr`	`u32`	The memory address where a corruption or inconsistency was first detected; 0 if the heap is healthy.
`bad_what`	`cstr`	A string description of the specific validation check that failed; NULL if the heap is healthy.
`chain_ok`	`bool`	True if the linked list of memory blocks is structurally sound (pointers are valid and contiguous).
`canary_ok`	`bool`	True if the memory guard patterns (canaries) surrounding blocks remain intact, indicating no buffer overflows.

Note:
This structure is populated by the system during a heap integrity check. It is typically allocated on the stack by the caller. The fields are read-only for the user; the system fills them to provide a snapshot of heap health.

Uso:
Use this structure when debugging memory-related crashes, heap corruption, or to monitor fragmentation levels in your application during development.

Esempio:

```c
ca_memory_check_t heap_status;

// Perform the check and populate the structure
if (ca_memory_check(&heap_status)) {
    if (!heap_status.chain_ok || !heap_status.canary_ok) {
        // Handle heap corruption error
        printf("Heap corruption at: %p\n", (void*)heap_status.bad_addr);
    } else {
        printf("Largest free block: %lu bytes\n", heap_status.largest_free);
    }
}
```

`ca_message_buffer_t`

Tipo: Struttura
File: `caos/inc/message.h:34:43`

```
typedef struct {
u8 *buffer;          /**< Data buffer */
u32 size;            /**< Total buffer size */
volatile u32 head;   /**< Write index */
volatile u32 tail;   /**< Read index */
volatile u32 used;   /**< Used bytes (header + payload) */
volatile u16 msg_count; /**< Number of messages in buffer */
ca_spinlock_irq_t lock; /**< IRQ-safe lock */
u32 waiting_task;    /**< Waiter HANDLE (ca_task_handle_t),
    CA_TASK_HANDLE_NONE = none */
} ca_message_buffer_t;
```

A thread-safe, circular buffer structure used for inter-task communication and message queuing in caOS.

Membri:

Nome	Tipo	Descrizione
`buffer`	`u8 *`	Pointer to the raw memory array allocated for storing message data. Must be large enough to hold all queued messages.
`size`	`u32`	The total capacity of the buffer in bytes. Must match the allocated size of the buffer pointer.
`head`	`volatile u32`	Current write index. Incremented by the producer; should not be modified manually by the user.
`tail`	`volatile u32`	Current read index. Incremented by the consumer; should not be modified manually by the user.
`used`	`volatile u32`	Current number of bytes occupied in the buffer. Used to track overflow conditions.
`msg_count`	`volatile u16`	The number of discrete messages currently stored in the buffer.
`lock`	`ca_spinlock_irq_t`	Internal spinlock used to ensure atomic access to the buffer across different task contexts and ISRs.
`waiting_task`	`u32`	Stores the handle of a task blocked waiting for data. Set to CA_TASK_HANDLE_NONE if no task is waiting.

Note:
The structure must be initialized before use. The 'buffer' memory must be allocated statically or globally to ensure it persists for the lifetime of the message buffer. The 'volatile' qualifiers are critical as they prevent the compiler from optimizing away reads/writes that occur across different execution contexts (tasks vs ISRs).

Uso:
Used as the primary data structure for message passing APIs in caOS. It is passed by reference to functions that push data into the queue or pull data out, ensuring thread-safe data exchange.

Esempio:

```
static u8 raw_data[256];
ca_message_buffer_t my_msg_queue = {
    .buffer = raw_data,
    .size = 256,
    .head = 0,
    .tail = 0,
    .used = 0,
    .msg_count = 0,
    .waiting_task = CA_TASK_HANDLE_NONE
};
```

```

/* The queue is now ready to be passed to caOS message API functions */
```

---

ca_mqtt_connected_cb_t

Tipo: Callback
File: caos/net/inc/mqtt_service.h:51:51

```
typedef void (*ca_mqtt_connected_cb_t)(void)
```

A callback function pointer type triggered by the MQTT service when a successful connection to the broker is established.

Membri:

Nome	Tipo	Descrizione
void	void	This callback takes no arguments and returns no value.

Note:
This callback is executed within the context of the MQTT service task. It must be non-blocking and should not perform heavy processing. Ensure that any shared resources accessed within this callback are protected by appropriate synchronization primitives like mutexes.

Uso:
Use this callback to trigger application-level logic immediately after the MQTT client successfully connects, such as subscribing to specific topics or publishing initial status messages.

Esempio:

```
void my_on_connect_handler(void) {
    // Logic to execute upon connection
    ca_mqtt_subscribe("sensors/data", 1);
}

// Registering the callback during MQTT configuration
ca_mqtt_config_t config = {
    .on_connected = my_on_connect_handler,
    // ... other config fields
};
ca_mqtt_init(&config);
```

---

ca_mqtt_disconnected_cb_t

Tipo: Callback
File: caos/net/inc/mqtt_service.h:62:62

```
typedef void (*ca_mqtt_disconnected_cb_t)(void)
```

A callback function type triggered by the MQTT service when the connection to the broker is lost.

Membri:

Nome	Tipo	Descrizione
void	void	This callback takes no arguments and returns nothing.

Note:

This callback is executed within the context of the MQTT service task. It must be kept short and non-blocking to avoid stalling the network stack. It is typically registered during the MQTT client initialization phase.

Uso:
Use this to implement reconnection logic, update UI status indicators, or trigger system-wide alerts when the MQTT connection drops.

Esempio:

```
void my_on_disconnect(void) {
    printf("MQTT connection lost! Attempting to reconnect...\n");
    // Trigger a flag for the main loop to handle reconnection
}

// During initialization:
ca_mqtt_config_t config = {
    .disconnected_cb = my_on_disconnect
};
```

---

ca_mqtt_message_cb_t

Tipo: Callback
File: caos/net/inc/mqtt_service.h:58:58

```
typedef void (*ca_mqtt_message_cb_t)(const char *topic,  u16 topic_len,
```

A callback function pointer type used to handle incoming MQTT messages received by the caOS MQTT client.

Membri:

Nome	Tipo	Descrizione
topic	const char *	Pointer to the string containing the MQTT topic. Note: this string is not guaranteed to be null-terminated.
topic_len	u16	The length of the topic string. Always use this value to process the topic safely.
payload	const uint8_t *	Pointer to the raw data buffer received in the MQTT message.
payload_len	u16	The size of the payload in bytes.

Note:
The callback is executed within the context of the MQTT service task. Keep the implementation short and non-blocking to avoid delaying other network operations. The memory pointed to by topic and payload is managed by the MQTT stack and is only valid for the duration of the callback execution.

Uso:
Used when subscribing to MQTT topics. You pass a function pointer of this type to the subscription API to define the logic that executes whenever a message arrives on a specific topic.

Esempio:

```
void my_mqtt_handler(const char *topic, u16 topic_len, const uint8_t *payload,
    u16 payload_len) { if (payload_len > 0) { printf("Received message on topic:
     %.*s\n", topic_len, topic); } } // Usage: ca_mqtt_subscribe(client, "
    sensors/temp", my_mqtt_handler);
```

---

ca_mutex_t

Tipo: Struttura
File: caos/inc/sync.h:51:58

```
typedef struct ca_mutex_s {
volatile u32 owner;          // owner's ca_task_handle_t while locked (
    not a
// thid: a position moves when a task below ends)
volatile u8 locked;          // 0 = free, 1 = locked
ca_wait_queue_t wait_queue;      // Tasks waiting
ca_spinlock_irq_t internal_lock; // Protects internal structure
struct ca_mutex_s *pi_next;   // next mutex in the owner's pi_held list
} ca_mutex_t;
```

A mutual exclusion primitive used to protect shared resources from concurrent access by multiple tasks.

Membri:

Nome	Tipo	Descrizione
owner	u32	Stores the handle of the task currently holding the mutex. Do not modify manually.
locked	u8	Status flag: 0 means the mutex is available, 1 means it is currently held by a task.
wait_queue	ca_wait_queue_t	Internal list of tasks blocked while waiting for this mutex to become available.
internal_lock	ca_spinlock_irq_t	A low-level spinlock used to ensure atomic operations on the mutex structure itself.
pi_next	struct ca_mutex_s *	Pointer used for Priority Inheritance (PI) tracking to link multiple mutexes held by the same task.

Note:
The mutex must be initialized before use. It is typically allocated in the global data segment or as part of a larger control block. Ownership is managed by the RTOS kernel; never attempt to manually set the 'owner' or 'locked' fields, as this will corrupt the scheduler's synchronization logic.

Uso:
Use this type to prevent race conditions when multiple tasks access the same peripheral or global variable. It is passed to synchronization APIs to lock and unlock critical sections.

Esempio:

```
ca_mutex_t my_mutex;

void task_function(void *arg) {
    ca_mutex_init(&my_mutex);

    if (ca_mutex_lock(&my_mutex, CA_WAIT_FOREVER) == CA_OK) {
        // Critical section: access shared resource here
        ca_mutex_unlock(&my_mutex);
    }
}
```

---

ca_net_buf_meta_t

Tipo: union
File: caos/net/inc/net_buf.h:106:110

```
typedef union {
ca_net_buf_rx_t rx;   /* RX path: filled by   L  2  L3L4   decode
       */
ca_net_buf_tx_t tx;   /* TX path: filled by upper layer
    */
u8              raw[52];
} ca_net_buf_meta_t;                                          /* 52
   bytes */
```

A union structure representing the metadata associated with a network buffer, used to store either RX or TX specific protocol information.

Membri:

Nome	Tipo	Descrizione
rx	ca_net_buf_rx_t	Metadata structure for incoming packets. Contains fields like protocol type, source/destination ports, and checksum status. Only valid when the buffer is in RX mode.
tx	ca_net_buf_tx_t	Metadata structure for outgoing packets. Contains fields like destination address and transmission flags. Only valid when the buffer is in TX mode.
raw	u8[52]	A raw byte array of 52 bytes used to access the memory directly or to ensure the union size is fixed for memory alignment and buffer pool management.

Note:
This union is part of the ca_net_buf_t structure. It does not require manual allocation as it is embedded within the buffer object. The developer must ensure they only access the member corresponding to the current direction of the packet (RX or TX) to avoid data corruption.

Uso:
Used by the network stack to track packet state as it moves through the OSI layers. You will typically access this when writing custom protocol handlers or inspecting packet headers in a callback.

Esempio:

```
ca_net_buf_t *buf = ca_net_buf_alloc();
if (buf != NULL) {
    // Accessing RX metadata for an incoming packet
    buf->meta.rx.proto = CA_NET_PROTO_UDP;
    buf->meta.rx.port = 8080;
    ca_net_process(buf);
}
```

---

ca_net_buf_pressure_t

Tipo: Struttura
File: caos/net/inc/net_buf.h:171:177

```
typedef struct {
u16 total;        /* NET_BUF_COUNT
    */
```

```
u16 free_now;     /* free buffers at the time of the call
    */
u16 free_min;     /* fewest ever free since the last reset  <-- the
   number */
u32 alloc_calls; /* allocations attempted since the last reset
    */
u32 alloc_fail;  /* of those, refused: the pool was empty
    */
} ca_net_buf_pressure_t;
```

A structure used to monitor the health and memory usage of the network buffer pool.

Membri:

Nome	Tipo	Descrizione
`total`	`u16`	The total number of network buffers available in the system pool.
`free_now`	`u16`	The number of buffers currently available for allocation.
`free_min`	`u16`	The lowest number of free buffers recorded since the last system reset; useful for detecting memory pressure spikes.
`alloc_calls`	`u32`	Total number of allocation requests made to the pool since the last reset.
`alloc_fail`	`u32`	Number of allocation requests that failed because the pool was empty.

Note:
This structure is populated by the system. It does not require manual allocation or initialization by the user. It is typically used to diagnose network stability issues or to tune the buffer pool size.

Uso:
Use this structure with ca_net_buf_pressure to retrieve current statistics. If the alloc_fail count is increasing, your system is running out of network buffers, which may lead to dropped packets or connection failures.

Esempio:

```
ca_net_buf_pressure_t stats;

/* Retrieve current network buffer statistics */
ca_net_buf_pressure(&stats);

/* Log the findings using the system printf */
ca_printf("Net Buffers: Total=%u, Free=%u, Min=%u, Failures=%lu\n",
          stats.total, stats.free_now, stats.free_min, stats.alloc_fail);

/* Optional: Reset the statistics counters if needed */
ca_net_buf_pressure_reset();
```

`ca_net_buf_rx_t`

Tipo: Struttura
File: `caos/net/inc/net_buf.h:68:78`

```
typedef struct {
u16    l3_off;   /* frame offset to L3 header: 14 no-VLAN, 18 with 802.1
   Q */
```

```
u16    l4_off;   /* frame offset to L4 header: l3_off + IP IHL; 0 if
    none */
ipv4_t src_ip;   /* IPv4 src (spa for ARP, 0 if non-IP)
     */
ipv4_t dst_ip;   /* IPv4 dst (tpa for ARP, 0 if non-IP)
     */
u16    src_port; /* UDP/TCP source port (0 if non UDP/TCP)
     */
u16    dst_port; /* UDP/TCP dest   port (0 if non UDP/TCP)
     */
u16    vlan_id;  /* 802.1Q VID (0 = untagged)
     */
u8     vlan_pcp; /* 802.1Q PCP (0-7)
     */
u8     ip_proto; /* IP_PROTO_ICMP=1 / UDP=17 / TCP=6; 0 if non-IP
    */
} ca_net_buf_rx_t;                                              /* 20
    bytes */
```

A metadata structure containing parsed network header offsets and addresses for an incoming packet buffer.

Membri:

Nome	Tipo	Descrizione
`l3_off`	`u16`	Byte offset from the start of the buffer to the Layer 3 (IP/ARP) header. Typically 14 for Ethernet II or 18 if 802.1Q VLAN tagged.
`l4_off`	`u16`	Byte offset to the Layer 4 (TCP/UDP) header. Set to 0 if the packet is not a transport layer protocol.
`src_ip`	`ca_ipv4_t`	Source IPv4 address extracted from the packet header. Set to 0 for non-IP packets.
`dst_ip`	`ca_ipv4_t`	Destination IPv4 address extracted from the packet header. Set to 0 for non-IP packets.
`src_port`	`u16`	Source port for TCP/UDP packets. Set to 0 if the protocol is not TCP or UDP.
`dst_port`	`u16`	Destination port for TCP/UDP packets. Set to 0 if the protocol is not TCP or UDP.
`vlan_id`	`u16`	The 802.1Q VLAN ID (VID). Value 0 indicates the packet is untagged.
`vlan_pcp`	`u8`	The 802.1Q Priority Code Point (PCP). Valid range is 0-7.
`ip_proto`	`u8`	The IP protocol number (e.g., 1 for ICMP, 6 for TCP, 17 for UDP). Set to 0 if not an IP packet.

Note:
This structure is typically populated by the caOS network stack driver during packet reception. It is read-only for the application layer. Do not manually modify these fields as they are used by the stack to route packets to the correct socket or handler.

Uso:
Used by network callback functions or packet processing tasks to inspect packet headers without manually parsing raw bytes. It allows for efficient filtering of incoming traffic based on IP or port.

Esempio:

```
void my_packet_handler(ca_net_buf_t *buf, ca_net_buf_rx_t *meta) {
    if (meta->ip_proto == 17 && meta->dst_port == 8080) {
```

```
        /* Process UDP packet destined for port 8080 */
        uint8_t *payload = (uint8_t *)buf->data + meta->l4_off + 8; /* Skip UDP
    header */
    }
}
```

---

ca_net_buf_t

Tipo: Struttura
File: caos/net/inc/net_buf.h:94:105

```
typedef struct {
/* ---- 64 byte metadata ---- */
u16                 next;      /* chained buffer index, NET_BUF_INVALID=
    end */
u16                 data_off;  /* byte offset from data[0] to payload
    start */
u16                 data_len;  /* payload length in bytes
     */
u8                  flags;     /* NET_BUF_F_*
     */
u8                  proto;     /* NET_PROTO_* set by L2 dispatcher
     */
u32                 timestamp; /* ca_os_tick() at frame reception
     */
ca_net_buf_meta_t meta;      /* L2/L3/L4 parse cache + TX routing info
     */
/* ---- 1984 byte data area ---- */
u8                  data[NET_BUF_DATA_SIZE];
} ca_net_buf_t;
```

A network buffer structure used to store packet data and metadata during transmission or reception in the caOS network stack.

Membri:

Nome	Tipo	Descrizione
next	u16	Index of the next buffer in a chain. Use NET_BUF_INVALID if this is the last buffer.
data_off	u16	Offset in bytes from the start of the data array to the actual payload. Must be within [0, NET_BUF_DATA_SIZE].
data_len	u16	Length of the payload in bytes. Must not exceed the remaining space in the data array.
flags	u8	Bitmask of NET_BUF_F_* flags indicating buffer state or packet properties.
proto	u8	Protocol identifier (NET_PROTO_*) assigned by the L2 dispatcher.
timestamp	u32	System tick value captured at the moment of frame reception.
meta	ca_net_buf_meta_t	Internal cache for L2/L3/L4 parsing results and routing information.
data	u8[NET_BUF_DATA_SIZE]	The raw memory buffer where packet data is stored.

Note:

Buffers are typically managed by the caOS network pool. Do not manually allocate these on the stack as they are large (2KB). Ownership is transferred to the network stack once passed to transmission functions.

Uso:
Used by network drivers and protocol layers to pass packet data through the stack. Always initialize the buffer via the network pool API before use.

Esempio:

```
ca_net_buf_t *buf = net_buf_alloc();
if (buf != NULL) {
    buf->data_off = 0;
    buf->data_len = 10;
    memcpy(&buf->data[buf->data_off], "HelloNet", 8);
    buf->next = NET_BUF_INVALID;
    net_send(buf);
}
```

---

ca_net_buf_tx_t

Tipo: Struttura
File: caos/net/inc/net_buf.h:81:86

```
typedef struct {
ipv4_t dst_ip;   /* IPv4 destination address
     */
u16    dst_port; /* UDP destination port
     */
u16    src_port; /* UDP source port
     */
mac_t  dst_mac;  /* resolved destination MAC
     */
} ca_net_buf_tx_t;                                    /* 14
   bytes */
```

A structure defining the network layer routing information required to transmit a UDP packet.

Membri:

Nome	Tipo	Descrizione
dst_ip	ca_ipv4_t	The target IPv4 address. Must be a valid unicast or broadcast address.
dst_port	u16	The destination UDP port number. Values 0-65535 are valid.
src_port	u16	The source UDP port number. Usually assigned by the application.
dst_mac	ca_mac_t	The resolved hardware MAC address of the destination. Must be populated via ARP resolution before transmission.

Note:
This structure is typically allocated on the stack by the application layer. It does not own any memory buffers; it acts as a header descriptor for the network stack to encapsulate data into an Ethernet frame. Ensure the dst_mac is correctly resolved via the ARP table before passing this struct to the transmission API.

Uso:

Used as a parameter in network transmission functions to specify the routing metadata for outgoing UDP datagrams.

Esempio:

```
ca_net_buf_tx_t tx_info = { .dst_ip = {192, 168, 1, 10}, .dst_port = 8080, .
    src_port = 5000, .dst_mac = {0x00, 0x11, 0x22, 0x33, 0x44, 0x55} };
```

---

ca_net_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:186:217

```
typedef struct {
ipv4_t         ip;     /* local IPv4 address */
ipv4_t         mask;   /* local subnet mask (0 = unknown, set by DHCP) */
mac_t          mac;    /* local MAC address (used for L2 filter) */
u16            mtu;            /* max TX payload bytes (0 = default 1500)
    */
u8             phy_nrst_port;  /* GPIO port index for PHY nRST (0xFF =
   not wired) */
u8             phy_nrst_pin;   /* GPIO pin 0..15 */
ca_arp_cfg_t   arp;
ca_udp_cfg_t   udp;
ca_icmp_cfg_t  icmp;
#if EN_NET_DHCP
ca_dhcp_cfg_t dhcp;
#endif
#if EN_NET_NTP
ca_ntp_cfg_t   ntp;
#endif
#if EN_NET_SYSLOG
ca_syslog_cfg_t syslog;
#endif
#if EN_NET_DNS
ca_dns_cfg_t   dns;
#endif
#if EN_NET_MDNS
ca_mdns_cfg_t mdns;
#endif
#if EN_NET_MQTT
ca_mqtt_cfg_t mqtt;
#endif
#if EN_NET_MODBUS
ca_modbus_cfg_t modbus;
#endif
} ca_net_cfg_t;
```

Configuration structure used to initialize the caOS network stack with hardware and protocol settings.

Membri:

Nome	Tipo	Descrizione
ip	ca_ipv4_t	The static IPv4 address for the device. If using DHCP, this may be ignored or overwritten.
mask	ca_ipv4_t	The subnet mask. Set to 0 if the network configuration is handled dynamically via DHCP.
mac	ca_mac_t	The unique 6-byte hardware MAC address for the Ethernet interface.
mtu	u16	Maximum Transmission Unit. Set to 0 to use the default value of 1500 bytes.
phy_nrst_port	u8	GPIO port index for the PHY reset pin. Use 0xFF if the PHY reset is not connected to a GPIO.
phy_nrst_pin	u8	GPIO pin number (0-15) for the PHY reset. Only relevant if phy_nrst_port is not 0xFF.
arp	ca_arp_cfg_t	Configuration parameters for the ARP protocol layer.
udp	ca_udp_cfg_t	Configuration parameters for the UDP protocol layer.
icmp	ca_icmp_cfg_t	Configuration parameters for the ICMP (ping) protocol layer.

Note:
This structure must be populated before calling the network initialization function. It is typically declared as a static constant or global variable to ensure it persists throughout the application lifecycle. Fields dependent on preprocessor macros (like DHCP or MQTT) are only available if those features are enabled in the project configuration.

Uso:
Use this struct to define the network identity and protocol behavior of your device. Pass a pointer to this structure to the network stack initialization function during system startup.

Esempio:

```
ca_net_cfg_t my_net_cfg = { .ip = {192, 168, 1, 10}, .mask = {255, 255, 255, 0}, .mac = {0x00, 0x08, 0xDC, 0x11, 0x22, 0x33}, .mtu = 1500, .phy_nrst_port = 0xFF }; ca_net_init(&my_net_cfg);
```

---

ca_net_filter_fn_t

Tipo: Callback
File: caos/net/inc/net.h:146:146

```
typedef void (*ca_net_filter_fn_t)(u16 buf_idx)
```

A callback function type used to inspect or modify network packets before they are processed by the stack.

Membri:

Nome	Tipo	Descrizione
buf_idx	u16	The index of the network buffer in the internal pool. Valid range is 0 to (MAX_NET_BUFFERS - 1). Passing an invalid index will cause an out-of-bounds access.

Note:

This callback is executed within the context of the network task. It must be kept short and non-blocking to avoid dropping incoming packets. The user does not allocate the buffer; they only receive the index to perform operations via the net_buf_get/set APIs.

Uso:
Used to implement custom packet filtering, firewalling, or packet inspection. It is registered with the network stack during initialization to intercept incoming traffic.

Esempio:

```
void my_packet_filter(u16 buf_idx) {
    u8 *data = net_buf_get_ptr(buf_idx);
    if (data[0] == 0xDE) {
        net_buf_drop(buf_idx);
    }
}

// Registration
ca_net_set_filter(my_packet_filter);
```

---

ca_net_handler_t

Tipo: Callback
File: caos/net/inc/net.h:61:61

```
typedef void (*ca_net_handler_t)(u16 buf_idx)
```

A callback function pointer type used by the network stack to process incoming network buffers.

Membri:

Nome	Tipo	Descrizione
buf_idx	u16	The index of the network buffer in the internal pool. Use this index with ca_net_buf_ptr to access the data.

Note:
This callback is typically invoked by the network stack when a packet is received. The handler is responsible for processing the data and must eventually call ca_net_buf_free to release the buffer back to the pool. Failure to free the buffer will lead to a memory leak in the network buffer pool.

Uso:
Used when registering custom protocol handlers or packet processors via ca_net_register. It allows the application to intercept specific network traffic.

Esempio:

```
void my_packet_processor(u16 buf_idx) {
    /* Get pointer to the buffer data using the provided index */
    void *data = ca_net_buf_ptr(buf_idx);

    /* Process the packet data here */
    ca_printf("Received packet at index %d\n", buf_idx);

    /* IMPORTANT: Always free the buffer after processing */
    ca_net_buf_free(buf_idx);
}

void setup_network(void) {
```

```
    /* Register the handler to process incoming packets */
    ca_net_register(my_packet_processor);
}
```

---

ca_net_mac_filter_fn_t

Tipo: Callback
File: caos/net/inc/net.h:182:182

```
typedef bool (*ca_net_mac_filter_fn_t)(u16 buf_idx, u8 iface)
```

A callback function type used to filter incoming network packets based on their MAC address or interface.

Membri:

Nome	Tipo	Descrizione
buf_idx	u16	The index of the network buffer containing the packet to be inspected.
iface	u8	The interface identifier where the packet was received.

Note:
The callback must return true to accept the packet or false to drop it. It is typically registered via ca_net_filter_set. Ensure the logic inside is fast, as it runs within the network processing context.

Uso:
Use this to implement custom firewall rules or packet filtering logic at the link layer. Register the function using ca_net_filter_set to enable the filtering mechanism.

Esempio:

```
bool my_mac_filter(u16 buf_idx, u8 iface) {
    /* Check if the packet at buf_idx should be allowed */
    /* ca_net_buf_ptr(buf_idx) could be used to inspect the header */
    return true;
}

void setup_filter(void) {
    /* Register the custom filter callback */
    ca_net_filter_set(my_mac_filter);
}
```

---

ca_net_queue_t

Tipo: Struttura
File: caos/net/inc/net_queue.h:27:31

```
typedef struct {
u16           buf[NET_QUEUE_DEPTH];
volatile u16 head;    /* consumer (net task) advances head */
volatile u16 tail;    /* producer (ISR)      advances tail */
} ca_net_queue_t;
```

A circular buffer structure used for thread-safe communication of network packets between an ISR and the network task.

Membri:

Nome	Tipo	Descrizione
`buf`	`u16[NET_QUEUE_DEPTH]`	The underlying storage array for packet descriptors or indices. Must be sized to NET_QUEUE_DEPTH.
`head`	`volatile u16`	The read index. Only the consumer (network task) should modify this value.
`tail`	`volatile u16`	The write index. Only the producer (ISR) should modify this value.

Note:
This structure implements a lock-free single-producer single-consumer (SPSC) queue. It relies on the volatile keyword to prevent compiler optimization of index access. The user is responsible for ensuring that the queue is not overflowed by the producer, as there is no built-in bounds checking in the struct itself.

Uso:
Use this type when you need to pass data from a hardware interrupt (e.g., Ethernet RX interrupt) to a background processing task without using heavy synchronization primitives like mutexes.

Esempio:

```c
ca_net_queue_t rx_queue;

void init_queue(void) {
    rx_queue.head = 0;
    rx_queue.tail = 0;
}

/* Inside ISR */
void HAL_ETH_RxCpltCallback(void) {
    rx_queue.buf[rx_queue.tail] = new_packet_id;
    rx_queue.tail = (rx_queue.tail + 1) % NET_QUEUE_DEPTH;
}

/* Inside Network Task */
void net_task(void *p) {
    while(1) {
        if(rx_queue.head != rx_queue.tail) {
            u16 packet = rx_queue.buf[rx_queue.head];
            rx_queue.head = (rx_queue.head + 1) % NET_QUEUE_DEPTH;
            process_packet(packet);
        }
    }
}
```

`ca_net_stats_t`

Tipo: Struttura
File: `caos/net/inc/net.h:68:78`

```c
typedef struct {
u32 rx_frames;         /* frames received */
u32 rx_dropped_pool;   /* dropped: pool exhausted */
u32 rx_dropped_small;  /* dropped: frame < 14 bytes */
u32 rx_no_handler;     /* received but no handler registered */
u32 tx_frames;         /* frames sent */
u32 tx_failed;         /* iface->send() returned false */
```

```
u32 err_bus;           /* CA_ETH_ERR_BUS events */
u32 err_rbu;           /* CA_ETH_ERR_RBU events */
u32 process_calls;     /* how many times ca_net_process() was called */
} ca_net_stats_t;
```

A structure containing diagnostic counters for the network stack, used to monitor traffic and identify packet loss or hardware errors.

Membri:

Nome	Tipo	Descrizione
rx_frames	u32	Total number of Ethernet frames successfully received.
rx_dropped_pool	u32	Frames dropped because the network buffer pool was exhausted.
rx_dropped_small	u32	Frames dropped because they were smaller than the minimum required size (14 bytes).
rx_no_handler	u32	Frames received for which no protocol handler was registered.
tx_frames	u32	Total number of Ethernet frames successfully sent.
tx_failed	u32	Frames that failed to send because the interface driver returned an error.
err_bus	u32	Count of CA_ETH_ERR_BUS hardware events.
err_rbu	u32	Count of CA_ETH_ERR_RBU hardware events.
process_calls	u32	Number of times the network processing loop was executed.

Note:
The structure is populated by the network stack. The user is responsible for providing a valid pointer to a ca_net_stats_t variable to the ca_net_stats() function, which will fill it with current values. It does not require manual allocation if declared on the stack.

Uso:
Use this type to perform periodic health checks on the network interface. It is typically called within a monitoring task to log network performance or detect connectivity issues.

Esempio:

```
ca_net_stats_t stats;

// Retrieve current network statistics
ca_net_stats(&stats);

// Log the number of received frames to the system console
ca_printf("Network RX frames: %u\n", stats.rx_frames);

// Check if there are any dropped frames due to pool exhaustion
if (stats.rx_dropped_pool > 0) {
    ca_printf("Warning: Dropped %u frames due to pool exhaustion!\n", stats.
    rx_dropped_pool);
}
```

---

ca_ntp_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:114:118

```c
typedef struct {
ca_ipv4_t           server_ip;    /* NTP server IPv4 */
u32              poll_ms;      /* poll interval in ms (0 = 64000 default)
    */
ca_ntp_synced_t on_synced;    /* called when time is updated (may be NULL
    ) */
} ca_ntp_cfg_t;
```

Configuration structure used to define the parameters for the NTP (Network Time Protocol) client service.

Membri:

Nome	Tipo	Descrizione
`server_ip`	`ca_ipv4_t`	The IPv4 address of the NTP server to synchronize with. Must be a valid network-byte-order address.
`poll_ms`	`u32`	The interval in milliseconds between synchronization attempts. If set to 0, the system defaults to 64000ms.
`on_synced`	`ca_ntp_synced_t`	A callback function pointer triggered whenever the system time is successfully updated. Can be set to NULL if no notification is required.

Note:
The structure is typically passed by value or pointer to the NTP initialization function. The user is responsible for allocating this struct, usually in static memory or on the stack before starting the network stack. Ensure the server_ip is reachable via the current network configuration.

Uso:
Use this structure when configuring the caOS network stack to enable automatic time synchronization. It is passed to the NTP client initialization routine to define the server target and the frequency of updates.

Esempio:

```c
void my_sync_callback(void) { /* Handle time update */ }

ca_ntp_cfg_t ntp_config = {
    .server_ip = {192, 168, 1, 10},
    .poll_ms = 30000,
    .on_synced = my_sync_callback
};

/* Pass ntp_config to the relevant caOS network initialization API */
```

`ca_ntp_fail_cb_t`

Tipo: Callback
File: `caos/net/inc/ntp_service.h:69:69`

```c
typedef void (*ca_ntp_fail_cb_t)(void)
```

A callback function type triggered by the NTP service when a time synchronization attempt fails.

Membri:

Nome	Tipo	Descrizione
`void`	`void`	The callback takes no arguments and returns no value.

Note:
This callback is executed within the context of the NTP service task. It must be kept short and non-blocking to avoid delaying network synchronization tasks. It is typically registered during the initialization of the NTP service.

Uso:
Use this to implement custom error handling or logging when the device fails to reach an NTP server, such as triggering a system status LED or attempting a network interface reset.

Esempio:

```
void my_ntp_error_handler(void) {
    log_error("NTP sync failed, retrying in 1 hour");
    status_led_blink(RED_COLOR);
}

// During system init:
ca_ntp_config_t config = {
    .fail_cb = my_ntp_error_handler
};
ca_ntp_init(&config);
```

---

ca_ntp_pkt_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:424:448

```
typedef struct {
u8  li_vn_mode;      /* Leap Indicator, Version, Mode */
u8  stratum;         /* Stratum */
u8  poll;            /* Poll interval */
i8  precision;       /* Precision */
u32 root_delay;      /* Root delay (32-bit) */
u32 root_dispersion; /* Root dispersion (32-bit) */
u32 ref_id;          /* Reference ID */

/* Reference timestamp (64-bit) */
u32 ref_ts_s;        /* Seconds */
u32 ref_ts_f;        /* Fraction */

/* Origin Timestamp (64-bit) - Here the server copies back your XMT */
u32 org_ts_s;
u32 org_ts_f;

/* Receive Timestamp (64-bit) - When the server received the packet */
u32 rec_ts_s;
u32 rec_ts_f;

/* Transmit Timestamp (64-bit) - When the server replied (THE TRUE TIME)
    */
u32 xmt_ts_s;
u32 xmt_ts_f;
} __attribute__((packed)) ca_ntp_pkt_t;
```

Represents a standard NTP (Network Time Protocol) packet structure used for network time synchronization.

Membri:

Nome	Tipo	Descrizione
`li_vn_mode`	`u8`	Bitfield containing Leap Indicator (2 bits), Version Number (3 bits), and Mode (3 bits).
`stratum`	`u8`	Indicates the distance from the reference clock (0 = unspecified, 1 = primary reference).
`poll`	`u8`	Maximum interval between successive messages, in log2 seconds.
`precision`	`i8`	Precision of the local clock, in log2 seconds.
`root_delay`	`u32`	Total round-trip delay to the reference clock, in 16.16 fixed-point format.
`root_dispersion`	`u32`	Maximum error relative to the reference clock, in 16.16 fixed-point format.
`ref_id`	`u32`	Reference clock identifier.
`ref_ts_s`	`u32`	Reference timestamp seconds part.
`ref_ts_f`	`u32`	Reference timestamp fraction part.
`org_ts_s`	`u32`	Origin timestamp seconds part (client transmit time).
`org_ts_f`	`u32`	Origin timestamp fraction part.
`rec_ts_s`	`u32`	Receive timestamp seconds part (server receive time).
`rec_ts_f`	`u32`	Receive timestamp fraction part.
`xmt_ts_s`	`u32`	Transmit timestamp seconds part (server transmit time).
`xmt_ts_f`	`u32`	Transmit timestamp fraction part.

Note:
The struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, which is critical for network protocol compliance. All multi-byte fields are typically expected in Network Byte Order (Big Endian).

Uso:
Used when constructing NTP request packets to be sent to a time server or when parsing the response packet received from a server to calculate network latency and clock offset.

Esempio:

```
ca_ntp_pkt_t ntp_req = {0};
ntp_req.li_vn_mode = 0x1B; // Version 3, Client mode
// ... populate other fields ...
// Send ntp_req via socket
// Receive response into another ca_ntp_pkt_t instance
```

`ca_ntp_sync_cb_t`

Tipo: Callback
File: `caos/net/inc/ntp_service.h:62:62`

```
typedef void (*ca_ntp_sync_cb_t)(u32 unix_time)
```

A callback function type triggered by the NTP service when a time synchronization event completes.

Membri:

Nome	Tipo	Descrizione
unix_time	u32	The current time in seconds since the Unix Epoch (January 1, 1970). If the value is 0, it indicates a synchronization failure.

Note:
This callback is executed within the context of the NTP service task. It must be kept short and non-blocking to avoid delaying network stack operations. The user does not allocate this; it is registered via the NTP service configuration.

Uso:
Use this callback to update the system RTC or application-level timestamps immediately after the device successfully synchronizes with an NTP server.

Esempio:

```
void my_ntp_callback(u32 unix_time) {
    if (unix_time > 0) {
        rtc_set_time(unix_time);
    }
}

// Registration
ca_ntp_config_t config = {
    .sync_cb = my_ntp_callback
};
ca_ntp_init(&config);
```

---

ca_ntp_synced_t

Tipo: Callback
File: caos/net/inc/net_cfg.h:113:113

```
typedef void (*ca_ntp_synced_t)(u32 unix_time);  /* called on sync */
```

A callback function pointer triggered by the caOS network stack when an NTP time synchronization event completes successfully.

Membri:

Nome	Tipo	Descrizione
unix_time	u32	The current time in seconds since the Unix Epoch (January 1, 1970). This value is provided by the NTP server and represents the synchronized system time.

Note:
This callback is executed within the context of the network task. It must be kept short and non-blocking to avoid delaying network packet processing. The user is responsible for assigning a valid function pointer to this type in the network configuration structure before the network stack is initialized.

Uso:
Used during the initialization of the caOS network stack. It allows the application to be notified immediately when the system clock has been updated via NTP, which is useful for logging, scheduling, or updating local RTC hardware.

Esempio:

```c
void my_ntp_callback(u32 unix_time) { printf("Time synchronized: %lu\n",
    unix_time); }

// In your network configuration setup:
ca_net_cfg_t config;
config.on_ntp_synced = my_ntp_callback;
ca_net_init(&config);
```

---

ca_opamp_input_t

Tipo: Enumerazione
File: caos/drivers/inc/opamp.h:30:33

```c
typedef enum {
CA_OPAMP_IN_PIN = 0,      /* OPAMPx_VINP pin */
CA_OPAMP_IN_DAC           /* DAC channel x, internal */
} ca_opamp_input_t;
```

Defines the signal source for the OPAMP non-inverting input, used during hardware configuration.

Membri:

Nome	Tipo	Descrizione
CA_OPAMP_IN_PIN	enum constant	Selects the physical external OPAMPx_VINP pin as the input source.
CA_OPAMP_IN_DAC	enum constant	Selects the internal DAC channel x output as the input source.

Note:
This enum is used to configure the internal routing of the STM32 OPAMP peripheral. It does not require allocation or freeing as it is a simple enumeration passed by value to initialization functions.

Uso:
Used in the ca_opamp_init function to specify whether the operational amplifier should sample an external voltage from a pin or an internal voltage generated by the DAC.

Esempio:

```c
#include "caos/drivers/inc/opamp.h"

void setup_opamp(void) {
    /* Configure OPAMP 1 to use the internal DAC as its input source */
    ca_opamp_input_t input_source = CA_OPAMP_IN_DAC;

    /* Initialize the OPAMP peripheral with the selected input */
    /* Note: ca_opamp_init is the standard function for this setup */
    ca_opamp_init(1, input_source);
}
```

---

ca_pool_cfg_t

Tipo: Struttura
File: caos/inc/pool.h:29:33

```
typedef struct {
u8            n_threads;   /**< number of worker threads (max 99) */
ca_stack_size_t stack_size;  /**< stack for each worker */
u16           priority;    /**< worker priority and one-shot fallback */
} ca_pool_cfg_t;
```

Configuration structure used to define the parameters for creating a thread pool in caOS.

Membri:

Nome	Tipo	Descrizione
`n_threads`	`u8`	The number of worker threads to spawn in the pool. Must be between 1 and 99. Setting this too high may lead to stack overflow or memory exhaustion.
`stack_size`	`ca_stack_size_t`	The size of the stack allocated for each individual worker thread. Ensure this is large enough for the tasks the threads will perform.
`priority`	`u16`	The scheduling priority assigned to the worker threads. Also acts as a fallback configuration for one-shot task execution.

Note:
This structure is typically passed by value to pool initialization functions. It does not own any memory itself; it is a template used by the kernel to allocate resources. Ensure the values are within system limits to avoid initialization failure.

Uso:
Use this structure when you need to initialize a thread pool to manage concurrent tasks. It is passed as an argument to the pool creation API to define the pool's footprint and scheduling behavior.

Esempio:

```
ca_pool_cfg_t my_pool_cfg = { .n_threads = 4, .stack_size = 512, .priority = 10
    }; ca_pool_init(&my_pool, &my_pool_cfg);
```

---

ca_pwr_info_t

Tipo: Struttura
File: `caos/drivers/inc/pwr.h:47:54`

```
typedef struct {
u32  sysclk_hz;        /*!< SYSCLK corrente */
u32  sysclk_max_hz;    /*!< SYSCLK nominale della scheda */
u8   vos;              /*!< voltage scaling corrente; 0xFF = non
   disponibile (F1) */
bool standby_resume;   /*!< true se il boot proviene da Standby */
u16  periph_on;        /*!< periferiche con clock RCC attivo */
u16  periph_total;     /*!< periferiche censite per la famiglia */
} ca_pwr_info_t;
```

A structure containing the current power and clock configuration status of the STM32 system.

Membri:

Nome	Tipo	Descrizione
sysclk_hz	u32	Current system clock frequency in Hertz. Used to calculate peripheral timings.
sysclk_max_hz	u32	Maximum rated frequency for the specific board. Used to validate overclocking limits.
vos	u8	Voltage scaling range index. Set to 0xFF if the hardware does not support dynamic voltage scaling (e.g., STM32F1).
standby_resume	bool	Flag indicating if the current execution started after waking up from Standby mode.
periph_on	u16	Bitmask or count of peripherals currently enabled in the RCC (Reset and Clock Control) registers.
periph_total	u16	Total number of peripherals available on the current MCU family.

Note:
This structure is typically populated by the caOS power driver. It is read-only for the application layer. Do not manually modify these fields as they reflect the hardware state managed by the kernel.

Uso:
Use this structure to perform runtime checks on system performance or to verify if the system is operating within safe power limits before enabling high-consumption peripherals.

Esempio:

```
ca_pwr_info_t pwr_status;

if (ca_pwr_get_info(&pwr_status) == CA_OK) {
    if (pwr_status.sysclk_hz < pwr_status.sysclk_max_hz) {
        // System is running underclocked
    }
    if (pwr_status.standby_resume) {
        // Perform specific wake-up initialization
    }
}
```

---

ca_pwr_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/pwr.h:28:32

```
typedef enum {
PWR_MODE_SLEEP = 0,     /*!< WFI semplice, clock attivi; wake da
    qualsiasi IRQ */
PWR_MODE_STOP,          /*!< deepsleep, regolatore LP; RAM/periferiche
    ferme, wake      prosegue */
PWR_MODE_STANDBY,       /*!< RAM persa; wake      reset (vedi
    standby_resume in ca_pwr_info_t) */
} ca_pwr_mode_t;
```

An enumeration defining the low-power states available for the STM32 microcontroller in caOS.

Membri:

Nome	Tipo	Descrizione
CA_PWR_MODE_SLEEP	enum constant	Executes WFI (Wait For Interrupt) with clocks active. The CPU stops, but peripherals continue running. Wakeup occurs on any interrupt.
CA_PWR_MODE_STOP	enum constant	Enters deepsleep mode with the low-power regulator. RAM and peripheral states are preserved, but clocks are stopped. Wakeup resumes execution from the point of entry.
PWR_MODE_STANDBY	enum constant	Enters the lowest power state. RAM content is lost. Wakeup triggers a system reset, effectively restarting the application.

Note:
This enum is used to configure the power management unit. Be aware that PWR_MODE_STANDBY causes a full system reset, meaning all volatile data will be lost unless specifically handled in the boot sequence.

Uso:
Used as an argument in power management API functions to transition the MCU into a specific low-power state to conserve battery life.

Esempio:

```
ca_pwr_mode_t target_mode = CA_PWR_MODE_STOP;

// Transition the system to STOP mode
ca_pwr_set_mode(target_mode);
```

---

ca_pwr_periph_t

Tipo: Struttura
File: caos/drivers/inc/pwr.h:40:45

```
typedef struct {
const char   *name;     /*!< nome periferica, es. "USART1" */
const char   *bus;      /*!< bus RCC, es. "APB2" */
volatile u32 *enr;      /*!< registro RCC xxxENR */
u32           mask;     /*!< bit di clock enable */
} ca_pwr_periph_t;
```

Defines the hardware configuration required to enable or disable the clock for a specific STM32 peripheral.

Membri:

Nome	Tipo	Descrizione
name	const char *	Human-readable identifier for the peripheral (e.g., "USART1"). Used primarily for debugging and logging.
bus	const char *	The RCC bus name (e.g., "APB1", "APB2", "AHB1"). Used by the driver to identify the clock domain.
enr	volatile u32 *	Pointer to the specific RCC Enable Register (e.g., &RCC->APB2ENR). Must be a valid volatile memory address.
mask	u32	The specific bit position within the ENR register that controls the peripheral clock. Must be a single bit mask.

Note:
This structure is typically defined as a constant global array in the board support package (BSP). It does not require dynamic allocation. The driver treats these as read-only configuration descriptors. Ensure the mask matches the STM32 reference manual for the specific MCU series.

Uso:
Used by the caOS power management driver to perform low-level clock gating. It is passed to internal driver functions to safely toggle peripheral clocks during initialization or power-saving transitions.

Esempio:

```
static const ca_pwr_periph_t my_uart_cfg = {
    .name = "USART1",
    .bus = "APB2",
    .enr = (volatile u32 *)&RCC->APB2ENR,
    .mask = RCC_APB2ENR_USART1EN
};

/* The driver uses this struct to enable the clock */
ca_pwr_enable(&my_uart_cfg);
```

---

ca_qspi_cfg_t

Tipo: Struttura
File: caos/drivers/inc/qspi.h:36:47

```
typedef struct {
u8  clk_div;       /*!< Prescaler: periph_clk / (clk_div + 1)  */
u8  flash_size;    /*!< log2(size_bytes) - 1, e.g. 23 per 16MB */
u8  addr_bytes;    /*!< Byte di indirizzo: 3 (24-bit) o 4 (32-bit) */
u8  dummy_cycles;  /*!< Cicli dummy per il comando di lettura    */
u8  data_lines;    /*!< Linee dati: 1=single, 2=dual, 4=quad    */
u8  cmd_read;      /*!< Comando lettura veloce, es. 0xEB o 0x6B */
u8  cmd_page_prog; /*!< Page program, es. 0x32 o 0x02           */
u8  cmd_sector_er; /*!< Sector erase, es. 0x20                  */
u8  cmd_wren;      /*!< Write enable, 0x06                       */
u8  cmd_rdsr;      /*!< Read status reg, 0x05                    */
} ca_qspi_cfg_t;
```

Configuration structure used to define the communication parameters and command set for an external QSPI flash memory.

Membri:

Nome	Tipo	Descrizione
clk_div	u8	Clock prescaler value. The resulting frequency is periph_clk / (clk_div + 1). Ensure this does not exceed the flash chip's maximum rated frequency.
flash_size	u8	Log2 of the total flash size in bytes minus 1. Example: 23 for 16MB (2^24 bytes).
addr_bytes	u8	Number of address bytes used for memory access. Valid values are 3 (24-bit addressing) or 4 (32-bit addressing).
dummy_cycles	u8	Number of dummy cycles required by the flash chip for read operations. Incorrect values will result in corrupted data reads.
data_lines	u8	Number of data lines used for transfer. 1 for Single SPI, 2 for Dual SPI, 4 for Quad SPI.
cmd_read	u8	Opcode for the fast read command (e.g., 0xEB for Quad I/O Read).
cmd_page_prog	u8	Opcode for the page program command (e.g., 0x32 for Quad Page Program).
cmd_sector_er	u8	Opcode for the sector erase command (e.g., 0x20 for 4KB sector erase).
cmd_wren	u8	Opcode for the Write Enable command, typically 0x06.
cmd_rdsr	u8	Opcode for reading the flash status register, typically 0x05.

Note:
This struct is passed by value or pointer to the QSPI driver initialization function. It must be populated based on the specific datasheet of the external flash chip connected to the STM32. The user is responsible for ensuring the values match the hardware capabilities.

Uso:
Used during the initialization phase of the QSPI peripheral to configure the communication protocol and command set required to interface with external flash memory.

Esempio:

```
ca_qspi_cfg_t my_flash_cfg = {
    .clk_div = 3,
    .flash_size = 23,
    .addr_bytes = 3,
    .dummy_cycles = 6,
    .data_lines = 4,
    .cmd_read = 0xEB,
    .cmd_page_prog = 0x32,
    .cmd_sector_er = 0x20,
    .cmd_wren = 0x06,
    .cmd_rdsr = 0x05
};

ca_qspi_init(&my_flash_cfg);
```

---

ca_qspi_pin_t

Tipo: Enumerazione
File: caos/drivers/inc/qspi.h:145:148

```
typedef enum {
CA_QSPI_PIN_CLK = 0, CA_QSPI_PIN_NCS, CA_QSPI_PIN_IO0,
CA_QSPI_PIN_IO1, CA_QSPI_PIN_IO2, CA_QSPI_PIN_IO3, CA_QSPI_PIN_COUNT
} ca_qspi_pin_t;
```

An enumeration representing the specific physical pins used by the QSPI peripheral interface.

Membri:

Nome	Tipo	Descrizione
CA_QSPI_PIN_CLK	enum constant	The Serial Clock pin.
CA_QSPI_PIN_NCS	enum constant	The Chip Select (active low) pin.
CA_QSPI_PIN_IO0	enum constant	Data line 0 (often MOSI in single-line mode).
CA_QSPI_PIN_IO1	enum constant	Data line 1 (often MISO in single-line mode).
CA_QSPI_PIN_IO2	enum constant	Data line 2.
CA_QSPI_PIN_IO3	enum constant	Data line 3.
CA_QSPI_PIN_COUNT	enum constant	Helper value representing the total number of pins; do not use as a valid pin index.

Note:
This enum is used to index into configuration arrays or pin mapping tables. CA_QSPI_PIN_COUNT is provided to allow for easy array sizing and bounds checking. Ensure that the hardware design matches the pin mapping expected by the driver.

Uso:
Used primarily in driver configuration structures or initialization functions where specific GPIO pins must be assigned to the QSPI peripheral functionality.

Esempio:

```
ca_qspi_pin_t pin = CA_QSPI_PIN_CLK; if (pin < CA_QSPI_PIN_COUNT) { /* Proceed
    with pin configuration */ }
```

---

ca_qspi_xfer_t

Tipo: Struttura
File: caos/drivers/inc/qspi.h:123:135

```
typedef struct {
u8         cmd;
u8         cmd_lines;     /* 0/1 = single, 2, 4 (QPI devices)  */
u8         addr_bytes;    /* 0 = cfg.addr_bytes                 */
u8         addr_lines;
u32        addr;
u8         dummy;
u8         data_lines;
bool       read;          /* data phase direction              */
u8        *rx;            /* read: destination                 */
const u8 *tx;             /* write: source                     */
u32        len;           /* data bytes (0 with data_lines 0) */
} ca_qspi_xfer_t;
```

A structure defining the parameters for a single QSPI bus transaction, used to configure command, address, and data phases.

Membri:

Nome	Tipo	Descrizione
`cmd`	`u8`	The 8-bit instruction code to send to the QSPI device.
`cmd_lines`	`u8`	Number of data lines used for the command phase. Valid: 0 or 1 (Single), 2, or 4 (QPI).
`addr_bytes`	`u8`	Number of address bytes to transmit. Set to 0 to use the default configured value.
`addr_lines`	`u8`	Number of data lines used for the address phase.
`addr`	`u32`	The memory address on the external device to access.
`dummy`	`u8`	Number of dummy cycles required by the device before data transfer.
`data_lines`	`u8`	Number of data lines used for the data phase. Set to 0 if no data phase is required.
`read`	`bool`	Direction of the data phase. True for read (device to MCU), false for write (MCU to device).
`rx`	`u8 *`	Pointer to the buffer where received data will be stored. Only used if read is true.
`tx`	`const u8 *`	Pointer to the buffer containing data to be sent. Only used if read is false.
`len`	`u32`	Number of bytes to transfer during the data phase.

Note:
The structure must be fully initialized before passing it to the driver. Ensure that the buffers pointed to by rx or tx remain valid for the duration of the transfer. This struct is typically allocated on the stack by the caller.

Uso:
Used as an argument for QSPI transfer functions to perform read/write operations on external flash or memory-mapped devices.

Esempio:

```
ca_qspi_xfer_t xfer = {0};
xfer.cmd = 0x03; // Read command
xfer.cmd_lines = 1;
xfer.addr = 0x000000;
xfer.addr_bytes = 3;
xfer.addr_lines = 1;
xfer.data_lines = 1;
xfer.read = true;
xfer.rx = my_buffer;
xfer.len = 256;
ca_qspi_transfer(&xfer);
```

`ca_queue_static_t`

Tipo: Struttura
File: `caos/inc/queue.h:59:69`

```
typedef struct {
u32 item_size;                // Single item size (bytes)
```

```
u32 max_items;                // Maximum capacity
volatile u32 count;           // Number of items present
volatile u32 head;            // Read index (consumer)
volatile u32 tail;            // Write index (producer)
ca_wait_queue_t wait_send;        // Task waiting for send (queue full)
ca_wait_queue_t wait_recv;        // Task waiting for receive (queue
    empty)
ca_spinlock_irq_t lock;           // Concurrent access protection
u8 buffer[];                  // Flexible array member (inline buffer)
} ca_queue_static_t;
```

A statically allocated FIFO queue structure used for thread-safe data exchange between tasks.

Membri:

Nome	Tipo	Descrizione
item_size	u32	Size of a single element in the queue in bytes.
max_items	u32	Maximum number of items the queue can hold.
count	volatile u32	Current number of items stored in the queue.
head	volatile u32	Index for the next read operation.
tail	volatile u32	Index for the next write operation.
wait_send	ca_wait_queue_t	Internal wait queue for tasks blocked while trying to send to a full queue.
wait_recv	ca_wait_queue_t	Internal wait queue for tasks blocked while trying to receive from an empty queue.
lock	ca_spinlock_irq_t	Spinlock used to ensure atomic access to the queue structure.
buffer	u8[]	Flexible array member acting as the storage area for queue items.

Note:
The structure must be declared with enough space for the buffer. Since it uses a flexible array member, you typically define a wrapper struct containing the queue and a static array. It is initialized via ca_queue_static_init. Ownership is usually shared between producer and consumer tasks.

Uso:
Use this when you need a fixed-size, thread-safe FIFO buffer. It is ideal for passing data between ISRs and tasks or between two tasks without dynamic memory allocation.

Esempio:

```
#define QUEUE_SIZE 10
#define ITEM_SIZE sizeof(u32)

struct {
    ca_queue_static_t q;
    u8 storage[QUEUE_SIZE * ITEM_SIZE];
} my_queue_wrapper;

void setup_queue(void) {
    // Initialize the queue with the buffer address and capacity
    ca_queue_static_init(&my_queue_wrapper.q, my_queue_wrapper.storage,
    QUEUE_SIZE, ITEM_SIZE);
}

void task_producer(void) {
    u32 data = 42;
    // Send data to the queue
    ca_queue_static_send(&my_queue_wrapper.q, &data);
```

```c
}

void task_consumer(void) {
    u32 data;
    // Receive data from the queue
    ca_queue_static_receive(&my_queue_wrapper.q, &data);
}
```

---

ca_queue_t

Tipo: Struttura
File: caos/inc/queue.h:43:53

```c
typedef struct {
u8 *buffer;                    // Buffer items (allocated on heap)
u32 item_size;                 // Single item size (bytes)
u32 max_items;                 // Maximum capacity
volatile u32 count;            // Number of items present
volatile u32 head;             // Read index (consumer)
volatile u32 tail;             // Write index (producer)
ca_wait_queue_t wait_send;        // Task waiting for send (queue full)
ca_wait_queue_t wait_recv;        // Task waiting for receive (queue
    empty)
ca_spinlock_irq_t lock;           // Concurrent access protection
} ca_queue_t;
```

A thread-safe FIFO queue structure used for inter-task communication and data buffering.

Membri:

Nome	Tipo	Descrizione
buffer	u8 *	Pointer to the memory area storing the queue items. Must be allocated before initialization.
item_size	u32	Size of a single element in bytes.
max_items	u32	Maximum number of items the queue can hold.
count	volatile u32	Current number of items in the queue.
head	volatile u32	Index for the next read operation.
tail	volatile u32	Index for the next write operation.
wait_send	ca_wait_queue_t	Internal wait queue for tasks blocked on a full queue.
wait_recv	ca_wait_queue_t	Internal wait queue for tasks blocked on an empty queue.
lock	ca_spinlock_irq_t	Spinlock used to ensure atomic access to the queue structure.

Note:
The structure is typically initialized via ca_queue_heap_init or ca_queue_static_init. The user is responsible for providing the memory buffer if using static initialization. The internal spinlock handles concurrency, making it safe to use between tasks and ISRs.

Uso:
Use this type to pass data between producer and consumer tasks. It is the core structure for the ca_queue_* API family, which provides thread-safe push and pop operations.

Esempio:

```c
#include "caos/inc/queue.h"

```

```c
#define QUEUE_SIZE 10
#define ITEM_SIZE sizeof(u32)

static ca_queue_t my_queue;
static u8 queue_buffer[QUEUE_SIZE * ITEM_SIZE];

void setup_queue(void) {
    /* Initialize the queue with a static buffer */
    ca_queue_static_init(&my_queue, queue_buffer, ITEM_SIZE, QUEUE_SIZE);
}

void producer_task(void) {
    u32 data = 42;
    /* Send data to the queue */
    ca_queue_static_send(&my_queue, &data);
}

void consumer_task(void) {
    u32 received_data;
    /* Receive data from the queue */
    ca_queue_static_receive(&my_queue, &received_data);
}
```

---

ca_recursive_mutex_t

Tipo: Struttura
File: caos/inc/sync.h:114:119

```c
typedef struct {
volatile u32 owner;          // owner's ca_task_handle_t while
    lock_count > 0
volatile u16 lock_count;     // Reentrancy counter (0 = free)
ca_wait_queue_t wait_queue;      // Tasks waiting
ca_spinlock_irq_t internal_lock; // Protects internal structure
} ca_recursive_mutex_t;
```

A synchronization primitive that allows the same task to acquire the lock multiple times without deadlocking itself.

Membri:

Nome	Tipo	Descrizione
owner	volatile u32	Stores the handle of the task currently holding the mutex. Only valid if lock_count > 0.
lock_count	volatile u16	Tracks the nesting level of the lock. Incremented on lock, decremented on unlock. 0 means the mutex is available.
wait_queue	ca_wait_queue_t	Internal list of tasks blocked waiting for this mutex.
internal_lock	ca_spinlock_irq_t	Low-level spinlock used to ensure atomic access to the structure members during state changes.

Note:
The recursive mutex must be initialized using ca_rmutex_init before use. It is typically allocated in the global data segment or as part of a larger control structure. The owner must be the same task that performs the unlock; attempting to unlock a mutex held by another task is undefined behavior.

Uso:

Use this when a task needs to call multiple functions that all require the same resource, and each function independently attempts to lock the resource. It prevents the task from blocking on its own held lock.

Esempio:

```c
#include "caos/inc/sync.h"

ca_recursive_mutex_t my_mutex;

void task_function(void) {
    ca_rmutex_init(&my_mutex);

    // First acquisition
    ca_rmutex_lock(&my_mutex);

    // Nested acquisition (allowed because it is recursive)
    ca_rmutex_lock(&my_mutex);

    // Perform protected operations here

    // Must unlock as many times as it was locked
    ca_rmutex_unlock(&my_mutex);
    ca_rmutex_unlock(&my_mutex);
}
```

`ca_route_entry_t`

Tipo: Struttura
File: `caos/net/inc/route_service.h:34:39`

```c
typedef struct {
ca_ipv4_t dst;
ca_ipv4_t mask;
ca_ipv4_t gw;
bool   active;
} ca_route_entry_t;
```

Represents a single entry in the system routing table used to determine the next hop for outgoing network packets.

Membri:

Nome	Tipo	Descrizione
`dst`	`ca_ipv4_t`	The destination IPv4 address or network prefix. Must be a valid IPv4 structure.
`mask`	`ca_ipv4_t`	The subnet mask associated with the destination. Defines the range of the network.
`gw`	`ca_ipv4_t`	The gateway (next hop) IP address. If the destination is local, this may be set to 0.0.0.0.
`active`	`bool`	Status flag. Set to true to enable the route, false to ignore it during lookup.

Note:
The routing table is typically managed by the network stack. Ensure that the mask is correctly aligned with the destination address to avoid routing loops or unreachable destinations. This struct is usually allocated in static memory or as part of a configuration array.

Uso:

Used when configuring static routes in the network stack or when querying the routing table to determine how to forward packets to specific subnets.

Esempio:

```
ca_route_entry_t my_route = {
    .dst = {192, 168, 1, 0},
    .mask = {255, 255, 255, 0},
    .gw = {192, 168, 1, 1},
    .active = true
};

// Add the route to the system table
ca_route_add(&my_route);
```

---

ca_rtc_alarm_cb_t

Tipo: Callback
File: `caos/drivers/inc/rtc.h:64:64`

```
typedef void (*ca_rtc_alarm_cb_t)(u8 alarm_id)
```

A function pointer type used to define a callback function that executes when a specific RTC alarm triggers.

Membri:

Nome	Tipo	Descrizione
`alarm_id`	`u8`	The identifier of the alarm that triggered the event. Valid values are typically 0 or 1 depending on the hardware configuration. Providing an invalid ID may lead to logic errors in the handler.

Note:
This callback is executed within the context of the RTC interrupt service routine (ISR). Therefore, the function must be kept extremely short, must not perform blocking operations (like waiting for semaphores or mutexes), and should avoid heavy processing. The user is responsible for defining the function and passing its address to the RTC driver configuration.

Uso:
Use this type when you need to perform an action (e.g., setting a flag, waking a task) immediately upon an RTC alarm event. It is typically passed as an argument during the RTC initialization or alarm configuration phase.

Esempio:

```
void my_alarm_handler(u8 alarm_id) {
    if (alarm_id == 0) {
        // Signal a task that the alarm has fired
        os_event_set(alarm_event_handle);
    }
}

// Usage during configuration
ca_rtc_config_alarm(0, &my_alarm_handler);
```

---

ca_rtc_alarm_t

Tipo: Struttura
File: caos/drivers/inc/rtc.h:52:61

```
typedef struct {
u8   sec;          /* 0  59    */
u8   min;          /* 0  59    */
u8   hour;         /* 0  23    */
u8   day;          /* 1  31    */
bool match_sec;    /* true = confronta secondi   */
bool match_min;    /* true = confronta minuti    */
bool match_hour;   /* true = confronta ore       */
bool match_day;    /* true = confronta giorno    */
} ca_rtc_alarm_t;
```

A configuration structure used to define the trigger conditions for a Real-Time Clock (RTC) alarm event.

Membri:

Nome	Tipo	Descrizione
sec	u8	Seconds value for the alarm. Valid range: 0-59. Ignored if match_sec is false.
min	u8	Minutes value for the alarm. Valid range: 0-59. Ignored if match_min is false.
hour	u8	Hours value for the alarm (24h format). Valid range: 0-23. Ignored if match_hour is false.
day	u8	Day of the month for the alarm. Valid range: 1-31. Ignored if match_day is false.
match_sec	bool	If true, the RTC will trigger the alarm when the current seconds match the 'sec' field.
match_min	bool	If true, the RTC will trigger the alarm when the current minutes match the 'min' field.
match_hour	bool	If true, the RTC will trigger the alarm when the current hours match the 'hour' field.
match_day	bool	If true, the RTC will trigger the alarm when the current day matches the 'day' field.

Note:
The structure is typically allocated on the stack by the user. The RTC hardware only checks fields where the corresponding match flag is set to true. If all match flags are false, the alarm behavior is undefined or may never trigger.

Uso:
Use this structure to configure an RTC alarm via the caOS driver API. Populate the fields, set the desired match flags, and pass the structure pointer to the RTC alarm configuration function.

Esempio:

```
ca_rtc_alarm_t my_alarm = { .sec = 30, .match_sec = true, .match_min = false, .
    match_hour = false, .match_day = false }; ca_rtc_set_alarm(&my_alarm);
```

---

ca_rtc_clk_src_t

Tipo: Enumerazione
File: caos/drivers/inc/rtc.h:30:34

```c
typedef enum {
CA_RTC_CLK_LSE = 1,    /* 32.768 kHz cristallo esterno */
CA_RTC_CLK_LSI = 2,    /* ~32 kHz RC interno (no cristallo) */
CA_RTC_CLK_HSE = 3,    /* HSE/32 */
} ca_rtc_clk_src_t;
```

Defines the clock source selection for the Real-Time Clock (RTC) peripheral.

Membri:

Nome	Tipo	Descrizione
`CA_RTC_CLK_LSE`	`enum value`	External 32.768 kHz crystal. Provides the highest accuracy for timekeeping.
`CA_RTC_CLK_LSI`	`enum value`	Internal Low-Speed RC oscillator. Does not require external components but is less accurate and temperature-dependent.
`CA_RTC_CLK_HSE`	`enum value`	High-Speed External clock divided by 32. Used when an external crystal is available but LSE is not populated.

Note:
The clock source must be configured before initializing the RTC peripheral. Changing the clock source while the RTC is running may cause unpredictable behavior or time drift. Ensure the hardware board actually supports the selected source (e.g., verify the presence of an LSE crystal).

Uso:
Used during the RTC initialization phase to tell the driver which hardware oscillator to use as the timebase for the RTC counter.

Esempio:

```c
ca_rtc_config_t rtc_cfg;
rtc_cfg.clk_src = CA_RTC_CLK_LSE;
rtc_cfg.format = CA_RTC_FORMAT_BIN;
ca_rtc_init(&rtc_cfg);
```

---

ca_rtc_dt_t

Tipo: Struttura
File: `caos/drivers/inc/rtc.h:37:45`

```c
typedef struct {
u8  sec;     /* 0  59    */
u8  min;     /* 0  59    */
u8  hour;    /* 0  23    */
u8  wday;    /* 1  7     (1=luned ) */
u8  day;     /* 1  31    */
u8  month;   /* 1  12    */
u8  year;    /* 0  99    (relativo al 2000) */
} ca_rtc_dt_t;
```

A structure representing a calendar date and time for the RTC peripheral.

Membri:

Nome	Tipo	Descrizione
sec	u8	Seconds, range 0-59. Values outside this range may cause hardware errors.
min	u8	Minutes, range 0-59.
hour	u8	Hours in 24-hour format, range 0-23.
wday	u8	Day of the week, range 1-7 where 1 is Monday.
day	u8	Day of the month, range 1-31.
month	u8	Month of the year, range 1-12.
year	u8	Year offset from 2000, range 0-99 (e.g., 24 represents 2024).

Note:
This struct is used to interface with the RTC hardware. It does not perform validation; ensure values are within the specified ranges before passing to driver functions to avoid undefined behavior in the RTC peripheral.

Uso:
Used as a parameter for RTC driver functions to set or retrieve the current system time and date.

Esempio:

```
ca_rtc_dt_t my_time = { .sec = 0, .min = 30, .hour = 14, .wday = 1, .day = 15, .month = 5, .year = 24 };
ca_rtc_set_time(&my_time);
```

---

ca_rwlock_t

Tipo: Struttura
File: caos/inc/sync.h:309:315

```
typedef struct {
volatile u16  readers;       /* active readers */
volatile u8   writer_active; /* writer in progress */
ca_wait_queue_t   read_queue;    /* waiting readers */
ca_wait_queue_t   write_queue;   /* waiting writers */
ca_spinlock_irq_t internal_lock;
} ca_rwlock_t;
```

A synchronization primitive that allows multiple concurrent readers or a single exclusive writer to access a shared resource.

Membri:

Nome	Tipo	Descrizione
readers	volatile u16	Counter of currently active readers. Incremented when a reader acquires the lock, decremented when released.
writer_active	volatile u8	Flag indicating if a writer currently holds the lock. 1 if active, 0 otherwise.
read_queue	ca_wait_queue_t	Queue of tasks blocked waiting to acquire the lock for reading.
write_queue	ca_wait_queue_t	Queue of tasks blocked waiting to acquire the lock for writing.
internal_lock	ca_spinlock_irq_t	Internal spinlock used to ensure atomic access to the rwlock structure members during state changes.

Note:
The structure must be initialized before use. It is typically allocated in static memory or as part of a larger control block. Ownership is shared among tasks accessing the resource. Do not modify members directly; use the provided ca_rwlock API functions to ensure thread safety.

Uso:
Use this when you have a data structure that is read frequently but updated rarely. It improves performance over a standard mutex by allowing multiple readers to access the data simultaneously while ensuring exclusive access for writers.

Esempio:

```
ca_rwlock_t my_data_lock;

void init_system(void) {
    ca_rwlock_init(&my_data_lock);
}

void task_reader(void) {
    ca_rwlock_read_lock(&my_data_lock);
    /* Perform read operations */
    ca_rwlock_read_unlock(&my_data_lock);
}

void task_writer(void) {
    ca_rwlock_write_lock(&my_data_lock);
    /* Perform write operations */
    ca_rwlock_write_unlock(&my_data_lock);
}
```

---

ca_sai_config_t

Tipo: Struttura
File: caos/drivers/inc/sai.h:55:59

```
typedef struct {
u32             fs_hz;    /* requested sample rate */
u8              bits;     /* 16, 24 or 32 data bits */
ca_sai_proto_t  proto;
} ca_sai_config_t;
```

Configuration structure for the Serial Audio Interface (SAI) peripheral, defining sample rate, bit depth, and protocol.

Membri:

Nome	Tipo	Descrizione
fs_hz	u32	The desired audio sample rate in Hertz (e.g., 44100, 48000). Must be supported by the hardware clock configuration.
bits	u8	Data word length in bits. Valid values are 16, 24, or 32.
proto	ca_sai_proto_t	The audio protocol mode (e.g., I2S, Left-Justified, Right-Justified). Must be a valid enum value from ca_sai_proto_t.

Note:
This struct is passed by value to the initialization function. It does not require dynamic allocation; it is typically declared on the stack before calling the initialization routine. Ensure the hardware clock is configured to support the requested fs_hz before calling ca_sai_init.

Uso:
Used as an input parameter for the ca_sai_init function to configure the SAI peripheral hardware registers before starting audio streaming.

Esempio:

```c
#include "caos/drivers/inc/sai.h"

void setup_audio(void) {
    ca_sai_config_t config;

    config.fs_hz = 48000;
    config.bits = 16;
    config.proto = CA_SAI_PROTO_I2S; // Assuming CA_SAI_PROTO_I2S is a valid enum member

    // Initialize the SAI peripheral with the defined configuration
    ca_sai_init(0, &config);
}
```

---

ca_sai_proto_t

Tipo: Enumerazione
File: caos/drivers/inc/sai.h:50:53

```c
typedef enum {
CA_SAI_I2S = 0,      /* Philips I2S: FS low = left, data one bit after FS */
CA_SAI_MSB           /* MSB-justified: FS high = left, data on the FS edge */
} ca_sai_proto_t;
```

Defines the digital audio protocol format (I2S or MSB-justified) used for SAI peripheral communication.

Membri:

Nome	Tipo	Descrizione
CA_SAI_I2S	enum value	Standard Philips I2S format. Frame Sync (FS) is low for the left channel; data is delayed by one bit clock cycle relative to FS.
CA_SAI_MSB	enum value	MSB-justified format. Frame Sync (FS) is high for the left channel; data is aligned exactly with the FS edge.

Note:
This enum is used to configure the hardware interface behavior. Ensure the selected protocol matches the requirements of your external audio codec or DAC/ADC chip. Incorrect selection will result in bit-shifted or garbled audio data.

Uso:
Used during the initialization of the SAI peripheral to specify the data alignment and framing protocol.

Esempio:

```c
#include "caos/drivers/inc/sai.h"

void setup_audio(void) {
    /* Define the protocol configuration */
```

```
    ca_sai_proto_t my_protocol = CA_SAI_I2S;

    /* Initialize the SAI peripheral with the chosen protocol */
    /* Note: ca_sai_init is the standard function to apply these settings */
    ca_sai_init(my_protocol);
}
```

---

ca_scheduler_tasks_info_mode

Tipo: Enumerazione
File: caos/inc/scheduler.h:419:425

```
typedef enum ca_scheduler_tasks_info_mode_tag{
CA_TH_INFO_DEFAULT=0,
CA_TH_INFO_FLAG,
TH_INFO_RUNTIME,
CA_TH_INFO_MEM,
TH_INFO_ASSERT
} ca_scheduler_tasks_info_mode;
```

An enumeration used to specify the level of detail or the specific category of information to retrieve when querying task statistics.

Membri:

Nome	Tipo	Descrizione
CA_TH_INFO_DEFAULT	enum constant	Retrieves standard task information. Use this for general monitoring.
CA_TH_INFO_FLAG	enum constant	Retrieves task flag status. Useful for debugging task state transitions.
TH_INFO_RUNTIME	enum constant	Retrieves execution time statistics. Essential for profiling and identifying bottlenecks.
CA_TH_INFO_MEM	enum constant	Retrieves stack usage and memory allocation data. Critical for preventing stack overflows.
TH_INFO_ASSERT	enum constant	Retrieves assertion-related diagnostic data. Used primarily for error tracking.

Note:
This enum is passed as an argument to scheduler diagnostic functions. It does not require manual allocation as it is a simple integer-based enumeration. Ensure the mode passed is supported by the specific diagnostic function being called to avoid undefined behavior.

Uso:
Use this type when calling scheduler diagnostic APIs to filter the output data. It allows you to request only the specific metrics needed, reducing overhead and keeping logs clean.

Esempio:

```
ca_scheduler_tasks_info_mode mode = CA_TH_INFO_MEM;
ca_scheduler_get_task_info(task_handle, mode, &buffer);
```

---

ca_secure_key_entry_t

Tipo: Struttura
File: caos/crypto/inc/keys_store.h:49:57

```
typedef struct {
u32 base_address;               /* Base address of the key within the
    common area */
u32 size;                       /* Key size */
u32 validity_start;             /* Packed validity start date (0 = no
    limit) */
u32 validity_stop;              /* Packed validity end date (0 = no
    limit) */
u8 is_allocated;                /* Flag: key allocated */
u8 access_mode;                 /* Current access mode */
u16 key_id;                     /* Unique key ID */
} ca_secure_key_entry_t;
```

Represents a metadata entry for a cryptographic key stored in the secure common area.

Membri:

Nome	Tipo	Descrizione
base_address	u32	The starting memory address of the key in the secure storage area. Must be aligned according to hardware requirements.
size	u32	The size of the key in bytes. Must match the actual key data length to prevent buffer overflows.
validity_start	u32	Packed date format representing when the key becomes active. Set to 0 to disable this check.
validity_stop	u32	Packed date format representing when the key expires. Set to 0 to disable this check.
is_allocated	u8	Boolean flag indicating if the entry is currently in use. 1 for allocated, 0 for free.
access_mode	u8	Bitmask defining read/write/execute permissions for the key. Incorrect values may cause hardware access faults.
key_id	u16	A unique identifier used to reference the key during cryptographic operations.

Note:
This structure is typically managed by the caOS key store manager. The application should treat this as read-only unless using specific management APIs. Ensure the memory region pointed to by base_address is initialized before setting is_allocated to 1.

Uso:
Used when querying the key store for metadata or when registering a new key into the secure storage system via the caOS crypto subsystem.

Esempio:

```
ca_secure_key_entry_t my_key = { .base_address = 0x08010000, .size = 32, .
    validity_start = 0, .validity_stop = 0, .is_allocated = 1, .access_mode = 0
    x01, .key_id = 0x0001 };
```

---

ca_secure_pipe_end_t

Tipo: Enumerazione
File: caos/crypto/inc/secure_pipe_service.h:37:40

```
typedef enum {
CA_SECURE_PIPE_A = 0U,
```

```
CA_SECURE_PIPE_B = 1U,
} ca_secure_pipe_end_t;
```

Identifies the specific endpoint (A or B) of a secure communication pipe.

Membri:

Nome	Tipo	Descrizione
`CA_SECURE_PIPE_A`	`enum constant`	Represents the first endpoint of the secure pipe. Must be used consistently with the peer configuration.
`CA_SECURE_PIPE_B`	`enum constant`	Represents the second endpoint of the secure pipe. Must be used consistently with the peer configuration.

Note:
This enum is used to distinguish between the two sides of a secure pipe connection. It is typically passed to initialization or communication functions to ensure data is routed to the correct logical channel. Ensure that the local and remote ends are configured to use opposite identifiers if required by the protocol.

Uso:
Used as a parameter in ca_secure_pipe_init, ca_secure_pipe_send, and ca_secure_pipe_recv to specify which pipe end is being accessed.

Esempio:

```c
#include "caos/crypto/inc/secure_pipe_service.h"

void setup_pipe(void) {
    ca_secure_pipe_end_t my_end = CA_SECURE_PIPE_A;

    /* Initialize the secure pipe service for endpoint A */
    ca_secure_pipe_init(my_end);

    uint8_t data[] = {0x01, 0x02, 0x03};
    /* Send data through the initialized pipe end */
    ca_secure_pipe_send(my_end, data, sizeof(data));
}
```

`ca_secure_pipe_t`

Tipo: Struttura
File: `caos/crypto/inc/secure_pipe_service.h:42:46`

```c
typedef struct {
ca_aes_channel_t ch;
ca_queue_t       q[2];    /* q[e]: ciphertext waiting to be read by end
    e */
bool             ready;
} ca_secure_pipe_t;
```

Represents a secure, encrypted communication channel between two endpoints using AES encryption.

Membri:

Nome	Tipo	Descrizione
ch	ca_aes_channel_t	The underlying AES cryptographic channel used for encrypting and decrypting data.
q	ca_queue_t[2]	Two internal queues: q[0] holds ciphertext for endpoint 0, q[1] for endpoint 1. Do not manipulate these directly.
ready	bool	Flag indicating if the pipe is fully initialized and ready for secure data transmission.

Note:
The structure must be initialized via ca_secure_pipe_init. The user is responsible for allocating the memory for the struct, but the internal queues and AES channel are managed by the ca_secure_pipe service. Ensure the pipe is deinitialized with ca_secure_pipe_deinit before freeing the memory to prevent resource leaks.

Uso:
Used to establish a secure, encrypted data stream between two tasks or system components. Use ca_secure_pipe_send to push data into the pipe and ca_secure_pipe_recv to retrieve decrypted data from the other end.

Esempio:

```c
#include "caos/crypto/inc/secure_pipe_service.h"

ca_secure_pipe_t my_pipe;

void setup_secure_channel(void) {
    /* Initialize the secure pipe structure */
    ca_secure_pipe_init(&my_pipe);
}

void send_data(const uint8_t *data, size_t len) {
    if (my_pipe.ready) {
        /* Send encrypted data through the pipe */
        ca_secure_pipe_send(&my_pipe, data, len);
    }
}

void receive_data(uint8_t *buffer, size_t max_len) {
    /* Retrieve and decrypt data from the pipe */
    ca_secure_pipe_recv(&my_pipe, buffer, max_len);
}
```

---

ca_sem_name_t

Tipo: union
File: caos/inc/sync.h:174:177

```c
typedef union ca_sem_name_u{
u8 name_c[8];
u64 name_l;
} ca_sem_name_t;
```

A union used to provide a unique identifier for a semaphore, allowing it to be represented as either an 8-character string or a 64-bit integer.

Membri:

Nome	Tipo	Descrizione
name_c	u8[8]	An array of 8 characters. Used for human-readable names. If the string is shorter than 8 bytes, ensure the remaining bytes are null-terminated.
name_l	u64	A 64-bit integer representation of the name. Useful for faster comparisons or when a numeric ID is preferred over a string.

Note:
This is a union, meaning both members share the same memory location. Writing to name_c will overwrite name_l and vice versa. It is typically passed by value to semaphore creation functions. No dynamic allocation is required as it is usually declared on the stack or as a static member.

Uso:
Used when initializing a semaphore to give it a unique name for debugging or tracking purposes within the RTOS kernel. It is passed as an argument to semaphore initialization functions to identify the resource.

Esempio:

```
ca_sem_name_t my_sem_name; my_sem_name.name_c[0] = 'U'; my_sem_name.name_c[1] = 'A'; my_sem_name.name_c[2] = 'R'; my_sem_name.name_c[3] = 'T'; my_sem_name.name_c[4] = '\0'; // Initialize semaphore with this name
```

---

ca_semaphore_t

Tipo: Struttura
File: caos/inc/sync.h:180:186

```
typedef struct __attribute__((aligned(4))) {
volatile u32 count;           // Available resource counter
u32 max_count;                // Maximum value
ca_wait_queue_t wait_queue;       // Tasks waiting
ca_spinlock_irq_t internal_lock; // Protects internal structure
ca_sem_name_t name;           // added for debug
} ca_semaphore_t;
```

A counting semaphore used to manage access to a limited number of shared resources or to synchronize tasks.

Membri:

Nome	Tipo	Descrizione
count	volatile u32	Current number of available resources. Decremented by wait, incremented by post.
max_count	u32	The upper limit for the semaphore count. Prevents overflow if set correctly.
wait_queue	ca_wait_queue_t	Internal list of tasks currently blocked waiting for this semaphore.
internal_lock	ca_spinlock_irq_t	Spinlock used to ensure atomic access to the semaphore structure members.
name	ca_sem_name_t	Optional string identifier for debugging purposes.

Note:
The semaphore must be initialized using ca_sem_init before use. It is typically allocated in the global data segment or as part of a larger control structure. Ownership is usually shared among

tasks that need to synchronize. Do not modify members directly; always use the ca_sem_* API functions.

Uso:
Use this type when you need to limit the number of tasks accessing a resource (e.g., a pool of buffers) or to signal between tasks. Use ca_sem_init to set the initial and maximum count, ca_sem_wait to acquire a resource, and ca_sem_post to release it.

Esempio:

```c
#include "caos/inc/sync.h"

ca_semaphore_t my_sem;

void task_init(void) {
    /* Initialize semaphore with 0 initial count and 5 max count */
    ca_sem_init(&my_sem, 0, 5);
}

void producer_task(void) {
    /* Signal that a resource is available */
    ca_sem_post(&my_sem);
}

void consumer_task(void) {
    /* Wait for a resource to become available */
    if (ca_sem_wait(&my_sem) == 0) {
        /* Resource acquired, perform work */
    }
}
```

---

ca_sha256_ctx_t

Tipo: Struttura
File: caos/crypto/inc/sha256.h:43:51

```c
typedef struct {
u32 state[8];                   /* Stato interno H0..H7 */
u64 bitlen;                     /* Lunghezza messaggio in bit (64 bit)
    */
u8  buffer[SHA256_BLOCK_SIZE];  /* Blocco parziale in accumulo */
u32 buflen;                     /* Byte validi in buffer */
u32 W[64];                      /* Message schedule     nel ctx, non su
    stack:
* la compressione SW    profonda e sui target
* senza HASH HW (F407) graverebbe lo stack. */
} ca_sha256_ctx_t;
```

A structure holding the internal state and working memory for the SHA-256 hashing algorithm.

Membri:

Nome	Tipo	Descrizione
`state`	`u32[8]`	The internal hash state (H0-H7). Initialized by ca_sha256_init and updated during processing.
`bitlen`	`u64`	Total length of the message processed so far in bits. Must be updated correctly to ensure final hash integrity.
`buffer`	`u8[64]`	Temporary storage for incoming data chunks that are not yet a full 64-byte block.
`buflen`	`u32`	Number of valid bytes currently stored in the buffer. Must be less than 64.
`W`	`u32[64]`	Message schedule array. Stored in the context to prevent stack overflow on memory-constrained targets like STM32F407.

Note:
The context must be initialized using ca_sha256_init before any update or finalization. It is typically allocated by the caller (on the stack or as a static/global variable). The user is responsible for the memory lifecycle of this struct. Do not manually modify these fields; use the provided API functions.

Uso:
Use this type to maintain the state of a SHA-256 calculation across multiple data chunks. It is passed as a pointer to ca_sha256_init, ca_sha256_update, and ca_sha256_final.

Esempio:

```
ca_sha256_ctx_t ctx; uint8_t hash[32]; ca_sha256_init(&ctx); ca_sha256_update(&ctx, (uint8_t*)"hello", 5); ca_sha256_final(&ctx, hash);
```

`ca_sha512_ctx_t`

Tipo: Struttura
File: `caos/crypto/inc/sha512.h:42:51`

```
typedef struct {
u64 state[8];                   /* Stato interno H0..H7 */
u64 bitlen_lo;                  /* Lunghezza messaggio in bit (parte bassa) */
u64 bitlen_hi;                  /* Lunghezza messaggio in bit (parte alta) */
u8  buffer[SHA512_BLOCK_SIZE];  /* Blocco parziale in accumulo */
u32 buflen;                     /* Byte validi in buffer */
u64 W[80];                      /* Message schedule     nel ctx, non su stack:
* 640B che graverebbero lo stack del task
* (Ed25519 chiama SHA-512 in profondit ). */
} ca_sha512_ctx_t;
```

A context structure used to maintain the internal state of a SHA-512 hashing operation across multiple data chunks.

Membri:

Nome	Tipo	Descrizione
state	u64[8]	The internal hash state (H0-H7). Initialized by the hash start function.
bitlen_lo	u64	Lower 64 bits of the total message length in bits. Used for final padding.
bitlen_hi	u64	Upper 64 bits of the total message length in bits.
buffer	u8[128]	Temporary storage for incoming data that does not yet fill a full 128-byte block.
buflen	u32	Number of valid bytes currently stored in the buffer. Must be less than 128.
W	u64[80]	Message schedule array. Stored here to prevent stack overflow in deep call stacks.

Note:
The structure must be initialized before use. It is typically allocated by the caller on the stack or as a static variable. It does not require dynamic memory allocation (malloc). Do not manually modify the fields after initialization.

Uso:
Use this structure when you need to hash data that arrives in fragments or is too large to fit in memory at once. Pass a pointer to this struct to the initialization, update, and finalization functions of the SHA-512 API.

Esempio:

```
ca_sha512_ctx_t ctx;
u8 hash_result[64];

ca_sha512_init(&ctx);
ca_sha512_update(&ctx, (u8*)"Hello ", 6);
ca_sha512_update(&ctx, (u8*)"World", 5);
ca_sha512_final(&ctx, hash_result);
```

---

ca_sp_link_stats_t

Tipo: Struttura
File: caos/crypto/inc/secure_pipe_service.h:135:142

```
typedef struct {
u32 hello_ok, hello_bad;        /* handshakes accepted / rejected
    */
u32 sessions;                   /* session keys derived
    */
u32 sealed, opened;
u32 tag_fail;                   /* forged, tampered or wrong key
    */
u32 replay;                     /* duplicate or out of the window
    */
u32 bad_format;                 /* wrong type, length, size
    */
} ca_sp_link_stats_t;
```

A structure containing diagnostic counters for a secure pipe link, used to monitor connection health and security events.

Membri:

Nome	Tipo	Descrizione
hello_ok	u32	Number of successful handshake attempts.
hello_bad	u32	Number of failed handshake attempts.
sessions	u32	Total number of session keys successfully derived.
sealed	u32	Number of packets successfully encrypted/sealed.
opened	u32	Number of packets successfully decrypted/opened.
tag_fail	u32	Count of authentication failures (forged or tampered data).
replay	u32	Count of packets rejected due to replay protection (duplicate or out-of-window).
bad_format	u32	Count of packets rejected due to malformed headers or invalid lengths.

Note:
This structure is typically populated by the secure pipe service. It is a read-only snapshot for the user. The application does not need to allocate memory for it; it is usually passed as a pointer to be filled by the underlying secure pipe driver.

Uso:
Use this to monitor the security integrity of a communication channel. If 'tag_fail' or 'replay' counters increase rapidly, it may indicate an active attack or severe synchronization issues between peers.

Esempio:

```c
#include "caos/crypto/inc/secure_pipe_service.h"

void monitor_link(void *pipe_handle) {
    ca_sp_link_stats_t stats;

    /* Clear the stats structure before use */
    ca_memzero(&stats, sizeof(ca_sp_link_stats_t));

    /*
     * Retrieve current statistics from the secure pipe.
     * Note: Assuming a hypothetical function to fetch stats exists
     * or the stats are retrieved via a specific service call.
     */
    if (stats.tag_fail > 0) {
        ca_printf("Security Alert: %u authentication failures detected!\n",
    stats.tag_fail);
    }
}
```

---

ca_sp_link_t

Tipo: Struttura
File: caos/crypto/inc/secure_pipe_service.h:144:163

```c
typedef struct {
u8              role;               /* 1 or 2
    */
bool            ready;              /* init done
    */
bool            up;                 /* session keys derived
    */
bool            my_fresh;           /* my_nonce sent, not paired yet
    */
```

```
bool           peer_pending;     /* peer nonce waiting for my hello()
    */
u8             my_nonce[16];
u8             peer_nonce[16];
void          *k_tx, *k_rx;      /* static direction keys (keys_store)
    */
void          *s_tx, *s_rx;      /* session AES contexts (keys_store),
   set
* up once per session, only the nonce
* changes per message                    */
ca_aes_ctx_t *ctx;               /* heap, set up per message
    */
ca_mutex_t     mutex;
u64            tx_ctr;           /* last counter sent
    */
u64            rx_top;           /* highest counter accepted
    */
u64            rx_win;           /* bit i = rx_top - i already accepted
    */
u32            session_ms;       /* ca_os_tick_ms() at derivation
    */
ca_sp_link_stats_t st;
} ca_sp_link_t;
```

Represents the state and cryptographic context of a secure communication pipe between two nodes.

Membri:

Nome	Tipo	Descrizione
role	u8	Defines the node role (1 or 2). Used to determine key derivation order.
ready	bool	Indicates if the structure has been successfully initialized.
up	bool	Indicates if session keys are derived and the pipe is ready for encrypted traffic.
my_fresh	bool	Flag indicating if the local nonce has been sent but pairing is incomplete.
peer_pending	bool	Flag indicating a peer nonce is waiting for a local hello response.
my_nonce	u8[16]	Local random nonce used for session key derivation.
peer_nonce	u8[16]	Remote peer nonce used for session key derivation.
k_tx, k_rx	void*	Pointers to static direction keys stored in the keys_store.
s_tx, s_rx	void*	Pointers to session AES contexts; initialized once per session.
ctx	ca_aes_ctx_t*	Pointer to heap-allocated AES context, re-initialized per message.
mutex	ca_mutex_t	Mutex to ensure thread-safe access to the pipe state.
tx_ctr	u64	Monotonic counter for outgoing messages to prevent replay attacks.
rx_top	u64	Highest sequence number accepted from the peer.
rx_win	u64	Sliding window bitmask for tracking accepted incoming sequence numbers.
session_ms	u32	Timestamp (ca_os_tick_ms) when the session was established.
st	ca_sp_link_stats_t	Statistics structure for tracking pipe performance and errors.

Note:
The structure must be initialized via ca_sp_link_init. The 'ctx' member is heap-allocated and must be managed carefully to avoid leaks. The mutex must be locked before accessing any fields during transmission or reception. Ownership of the link structure is typically held by the task managing the secure connection.

Uso:
Used by the secure pipe service to maintain session state. It is passed as a handle to functions like ca_sp_link_hello, ca_sp_link_accept, and ca_sp_link_seal to perform cryptographic operations and manage the secure channel lifecycle.

Esempio:

```
ca_sp_link_t my_pipe;
ca_mutex_t pipe_mutex;

/* Initialize the mutex before the pipe */
ca_mutex_init(&pipe_mutex);

/* Initialize the secure pipe link structure */
ca_sp_link_init(&my_pipe, 1, &pipe_mutex);

/* Check if the pipe is ready for communication */
if (ca_sp_link_is_up(&my_pipe)) {
    /* Proceed with secure data transmission */
    ca_sp_link_seal(&my_pipe, buffer, length);
```

```
} else {
    /* Initiate handshake */
    ca_sp_link_hello(&my_pipe);
}
```

---

ca_spi_br_t

Tipo: Enumerazione
File: caos/drivers/inc/spi.h:43:52

```
typedef enum {
SPI_BR_DIV2   = 0,   /* FPCLK / 2   */
SPI_BR_DIV4   = 1,   /* FPCLK / 4   */
SPI_BR_DIV8   = 2,   /* FPCLK / 8   */
SPI_BR_DIV16  = 3,   /* FPCLK / 16  */
SPI_BR_DIV32  = 4,   /* FPCLK / 32  */
SPI_BR_DIV64  = 5,   /* FPCLK / 64  */
SPI_BR_DIV128 = 6,   /* FPCLK / 128 */
SPI_BR_DIV256 = 7,   /* FPCLK / 256 */
} ca_spi_br_t;
```

Defines the baud rate prescaler for the SPI peripheral, determining the communication speed relative to the peripheral clock.

Membri:

Nome	Tipo	Descrizione
CA_SPI_BR_DIV2 to CA_SPI_BR_DIV256	enum constant	Sets the divisor for the SPI peripheral clock (FP CLK). Higher divisors result in slower communica tion speeds. Ensure the resulting frequency doe not exceed the maximum rating of the connecte slave device.

Note:
This enum is used to configure the hardware clock divider. The actual SPI frequency is calculated as FPCLK / (2^n), where n is the value of the enum. It must be set during the SPI initialization phase before the peripheral is enabled.

Uso:
Used within the SPI configuration structure passed to the initialization function to set the desired bit rate for synchronous serial communication.

Esempio:

```
ca_spi_cfg_t my_spi_cfg = { .baud_rate = CA_SPI_BR_DIV16, .mode =
    SPI_MODE_MASTER, .data_size = SPI_DATASIZE_8BIT };
```

---

ca_spi_config_t

Tipo: Struttura
File: caos/drivers/inc/spi.h:57:69

```
typedef struct {
u8                spi_num;     /* 1=SPI1, 2=SPI2, 3=SPI3          */
ca_spi_br_t       br;          /* clock prescaler (master only)    */
u8                cpol;        /* 0=idle low,  1=idle high         */
```

```
u8                  cpha;         /* 0=1st edge,  1=2nd edge          */
bool                master;       /* true=master, false=slave         */
u16                 frame_size;   /* byte per frame (slave IRQ mode)  */
ca_spi_slave_cb_t   on_rx;        /* NULL=polling, non-NULL=IRQ slave */
bool                alternate_gpio; /* true=mappatura pin alternativa   */
bool                manage_cs;    /* true=driver gestisce CS via GPIO */
gpio_port_t         cs_port;      /* porta GPIO del CS                */
gpio_pin_t          cs_pin;       /* pin GPIO del CS                  */
} ca_spi_config_t;
```

Configuration structure used to define the hardware parameters and operating mode of an SPI peripheral.

Membri:

Nome	Tipo	Descrizione
spi_num	u8	The hardware SPI instance index. Valid values are 1, 2, or 3. Incorrect values will cause driver initialization to fail.
br	ca_spi_br_t	Baud rate prescaler for master mode. Determines the SPI clock speed. Must be set according to the peripheral's maximum clock frequency.
cpol	u8	Clock polarity: 0 for idle low, 1 for idle high. Must match the slave device's requirements.
cpha	u8	Clock phase: 0 for first edge capture, 1 for second edge capture. Must match the slave device's requirements.
master	bool	Sets the SPI role. True for master (generates clock), false for slave (receives clock).
frame_size	u16	Expected number of bytes per frame when operating in slave IRQ mode.
on_rx	ca_spi_slave_cb_t	Callback function pointer for slave IRQ mode. If set to NULL, the driver operates in polling mode.
alternate_gpio	bool	If true, uses the alternate pin mapping for the SPI peripheral pins.
manage_cs	bool	If true, the driver automatically toggles the Chip Select pin defined by cs_port and cs_pin.
cs_port	ca_gpio_port_t	GPIO port identifier for the Chip Select signal.
cs_pin	ca_gpio_pin_t	GPIO pin number for the Chip Select signal.

Note:
This structure is typically allocated on the stack before calling the SPI initialization function. Ensure all fields are initialized to avoid undefined behavior. If manage_cs is true, ensure the GPIO port and pin are correctly configured as outputs before SPI initialization.

Uso:
Used as an input parameter for the SPI driver initialization function to configure the peripheral hardware settings before any data transfer occurs.

Esempio:

```
ca_spi_config_t spi_cfg = { .spi_num = 1, .br = CA_SPI_BR_DIV8, .cpol = 0, .cpha
    = 0, .master = true, .manage_cs = true, .cs_port = GPIOA, .cs_pin =
   GPIO_PIN_4 }; ca_spi_init(&spi_cfg);
```

ca_spi_slave_cb_t

Tipo: Callback
File: caos/drivers/inc/spi.h:55:55

```
typedef void (*ca_spi_slave_cb_t)(u8 spi_num, const u8 *data, u16 len)
```

A function pointer type used as a callback to handle incoming data when the STM32 is configured as an SPI slave.

Membri:

Nome	Tipo	Descrizione
spi_num	u8	The index of the SPI peripheral that received the data (e.g., 1 for SPI1). Must match the hardware peripheral ID.
data	const u8 *	Pointer to the buffer containing the received bytes. This memory is managed by the driver and should be treated as read-only.
len	u16	The number of bytes received in the current transaction. Must be used to avoid buffer overflows when processing data.

Note:
This callback is executed in the context of the SPI interrupt service routine. Keep the logic inside this function extremely brief to avoid blocking other system tasks. Do not perform blocking operations or complex calculations here. The pointer 'data' is only valid for the duration of the callback execution.

Uso:
Used when initializing an SPI slave interface via the caOS driver. You assign a function matching this signature to the driver configuration structure so the system knows where to route incoming SPI data.

Esempio:

```
void my_spi_handler(u8 spi_num, const u8 *data, u16 len) {
    if (len > 0) {
        process_received_packet(data, len);
    }
}

// During initialization
ca_spi_config_t config = {
    .slave_callback = my_spi_handler,
    // ... other config fields
};
ca_spi_init(1, &config);
```

---

ca_spinlock_irq_t

Tipo: Struttura
File: caos/inc/atomic.h:48:51

```
typedef struct ca_spinlock_irq_s{
volatile u32 key;
u32 irq_state;
}   ca_spinlock_irq_t;
```

A spinlock structure that automatically disables interrupts to ensure thread safety in both task and ISR contexts.

Membri:

Nome	Tipo	Descrizione
`key`	`volatile u32`	Internal flag used to track the lock state. Must be initialized to 0.
`irq_state`	`u32`	Storage for the CPU interrupt mask state saved during lock acquisition to restore it correctly upon release.

Note:
This structure must be initialized using ca_spinlock_irq_init before use. It is typically allocated as a static variable or within a global control block. It is designed to prevent deadlocks when a resource is shared between tasks and interrupt service routines (ISRs).

Uso:
Use this type when you need to protect a shared resource (like a global variable or hardware peripheral) that is accessed by both normal tasks and ISRs. Use ca_spinlock_lock_irq to acquire and ca_spinlock_unlock_irq to release.

Esempio:

```c
static ca_spinlock_irq_t my_lock;

void init_resource(void) {
    ca_spinlock_irq_init(&my_lock);
}

void update_shared_data(void) {
    ca_spinlock_lock_irq(&my_lock);
    /* Perform critical section operations here */
    ca_spinlock_unlock_irq(&my_lock);
}
```

`ca_spinlock_t`

Tipo: Struttura
File: `caos/inc/atomic.h:40:42`

```c
typedef struct  ca_spinlock_s{
volatile u32 key;
}  ca_spinlock_t;
```

A lightweight synchronization primitive used to protect shared resources by busy-waiting.

Membri:

Nome	Tipo	Descrizione
`key`	`volatile u32`	Internal state of the spinlock. Must be treated as opaque; do not modify directly.

Note:
Spinlocks are intended for very short critical sections. They do not put the task to sleep, meaning the CPU will spin in a loop until the lock is acquired. Using them for long operations will starve other tasks and degrade system performance. Always initialize before use.

Uso:

Use when you need to protect data accessed by both ISRs and tasks, or between tasks where the critical section is extremely short. Use ca_spinlock_lock_irq and ca_spinlock_unlock_irq for ISR-safe protection.

Esempio:

```
#include "caos/inc/atomic.h"

static ca_spinlock_t my_lock;
static int shared_resource = 0;

void update_resource(int value) {
    /* Initialize the spinlock before first use */
    ca_spinlock_irq_init(&my_lock);

    /* Acquire lock and disable interrupts */
    ca_spinlock_lock_irq(&my_lock);

    shared_resource = value;

    /* Release lock and restore interrupts */
    ca_spinlock_unlock_irq(&my_lock);
}
```

---

ca_stream_buffer_t

Tipo: Struttura
File: caos/inc/stream.h:30:39

```
typedef struct {
u8 *buffer;          /**< Data buffer */
u32 size;            /**< Buffer size */
volatile u32 head;   /**< Write index */
volatile u32 tail;   /**< Read index */
volatile u32 count; /**< Bytes in buffer */
ca_spinlock_irq_t lock; /**< IRQ-safe lock */
u32 waiting_task;    /**< Waiter HANDLE (ca_task_handle_t),
   CA_TASK_HANDLE_NONE = none */
u32 trigger_level;   /**< Minimum bytes to wake receiver */
} ca_stream_buffer_t;
```

A thread-safe, circular FIFO buffer used for streaming byte-oriented data between tasks or ISRs.

Membri:

Nome	Tipo	Descrizione
buffer	u8 *	Pointer to the allocated memory block used for storage.
size	u32	Total capacity of the buffer in bytes.
head	volatile u32	Index where the next byte will be written.
tail	volatile u32	Index where the next byte will be read.
count	volatile u32	Current number of bytes stored in the buffer.
lock	ca_spinlock_irq_t	Internal spinlock to ensure atomic access during concurrent operations.
waiting_task	u32	Handle of the task waiting for data; set to CA_TASK_HANDLE_NONE if no task is waiting.
trigger_level	u32	Threshold of bytes required to trigger a task wake-up event.

Note:
The structure must be initialized via ca_stream_init before use. The memory for the buffer must be allocated by the user (e.g., via ca_memory_allocate) and must persist for the lifetime of the stream. The 'volatile' fields ensure that the compiler does not optimize away memory accesses, which is critical for ISR-to-task communication.

Uso:
Used for buffering data streams (e.g., UART RX/TX, network data). Use ca_stream_send/ca_stream_receive for data transfer, and ca_stream_set_trigger to define when a blocked task should be unblocked.

Esempio:

```
ca_stream_buffer_t my_stream;
u8 my_raw_buffer[128];

void setup_stream(void) {
    /* Initialize the stream with a 128-byte buffer */
    ca_stream_init(&my_stream, my_raw_buffer, 128);
    /* Wake up task when at least 10 bytes are available */
    ca_stream_set_trigger(&my_stream, 10);
}

void task_producer(void) {
    u8 data = 0xAA;
    ca_stream_send(&my_stream, &data, 1);
}

void task_consumer(void) {
    u8 rx_byte;
    /* Wait for data and receive it */
    if (ca_stream_receive(&my_stream, &rx_byte, 1) > 0) {
        /* Process byte */
    }
}
```

---

ca_sw_timer_handle_t

Tipo: simple
File: caos/inc/sw_timer.h:77:77

```
typedef u8 ca_sw_timer_handle_t
```

A unique identifier (handle) used to reference and manage a software timer within the caOS RTOS.

Membri:

Nome	Tipo	Descrizione
`ca_sw_timer_handle_t`	`u8`	An 8-bit unsigned integer acting as an index or ID for a specific software timer. Valid values range from 0 to the maximum number of timers configured in the system.

Note:
This type is a simple alias for an unsigned 8-bit integer. It does not represent the timer object itself, but rather a reference to it. The handle is typically returned by the timer creation function and must be stored by the user to perform subsequent operations like starting, stopping, or deleting the timer. It is not dynamically allocated; it is a stack or global variable.

Uso:
Use this type whenever you need to interact with a software timer after it has been created. It is passed as the first argument to functions such as ca_sw_timer_start, ca_sw_timer_stop, and ca_sw_timer_delete to specify which timer instance to target.

Esempio:

```
ca_sw_timer_handle_t my_timer_id;

void setup_timer(void) {
    // Create a timer and store the returned handle
    my_timer_id = ca_sw_timer_create(1000, CA_TIMER_PERIODIC, my_callback_func);

    if (my_timer_id != CA_INVALID_TIMER_HANDLE) {
        ca_sw_timer_start(my_timer_id);
    }
}
```

`ca_sw_timer_mode_t`

Tipo: Enumerazione
File: `caos/inc/sw_timer.h:53:56`

```
typedef enum {
CA_TIMER_ONE_SHOT = 0,   /* Single execution */
CA_TIMER_PERIODIC = 1    /* Automatic repetition */
} ca_sw_timer_mode_t;
```

An enumeration defining the execution behavior of a software timer in caOS.

Membri:

Nome	Tipo	Descrizione
`CA_TIMER_ONE_SHOT`	`enum constant`	The timer callback will execute exactly once after the timeout period expires. The timer stops automatically after the first trigger.
`CA_TIMER_PERIODIC`	`enum constant`	The timer callback will execute repeatedly at the specified interval until explicitly stopped by the user.

Note:

This enum is used as a configuration parameter during timer creation. It does not require manual memory management as it is a simple integer-based enumeration. Ensure the mode is selected based on whether you need a single event or a recurring task.

Uso:
Used when initializing a software timer structure to determine if the timer should restart itself automatically after expiration. Pass this value to the timer creation API to set the operational mode.

Esempio:

```
ca_sw_timer_t my_timer;
ca_sw_timer_init(&my_timer, CA_TIMER_PERIODIC, my_callback_function, NULL);
ca_sw_timer_start(&my_timer, 1000); // Starts a periodic timer with 1000ms
    interval
```

---

ca_sw_timer_state_t

Tipo: Enumerazione
File: caos/inc/sw_timer.h:59:63

```
typedef enum {
CA_TIMER_STOPPED = 0,
CA_TIMER_RUNNING = 1,
CA_TIMER_EXPIRED = 2
} ca_sw_timer_state_t;
```

Represents the current operational status of a software timer within the caOS RTOS.

Membri:

Nome	Tipo	Descrizione
CA_TIMER_STOPPED	enum constant	The timer is inactive and not counting. It will not trigger any callbacks.
CA_TIMER_RUNNING	enum constant	The timer is currently active and counting down towards its expiration time.
CA_TIMER_EXPIRED	enum constant	The timer has reached zero and the associated callback has been executed or is pending execution.

Note:
This enum is typically returned by status-check functions to allow the application to verify if a timer is safe to reconfigure or restart. It is a read-only state indicator managed internally by the caOS kernel.

Uso:
Use this type when you need to poll the status of a software timer before performing operations like starting, stopping, or deleting the timer instance to avoid race conditions or invalid state transitions.

Esempio:

```
ca_sw_timer_state_t status = ca_sw_timer_get_state(my_timer_handle);

if (status == CA_TIMER_STOPPED) {
    ca_sw_timer_start(my_timer_handle);
} else if (status == CA_TIMER_RUNNING) {
    // Timer is busy, wait or perform other tasks
}
```

---

ca_sw_timer_t

Tipo: Struttura
File: caos/inc/sw_timer.h:66:74

```
typedef struct {
u32 period_ms;              /* Period in ms */
u32 remaining_ms;           /* Remaining time */
ca_timer_callback_t cb;     /* Callback */
void *cb_arg;               /* Callback argument */
ca_sw_timer_mode_t mode;          /* One-shot or periodic */
ca_sw_timer_state_t state;        /* Current state */
u8 active;                  /* 1 = slot used, 0 = free */
} ca_sw_timer_t;
```

A software timer structure used to schedule periodic or one-shot tasks without blocking the CPU.

Membri:

Nome	Tipo	Descrizione
period_ms	u32	The timer interval in milliseconds. Must be greater than 0.
remaining_ms	u32	Internal counter tracking time left until expiration. Do not modify manually.
cb	ca_timer_callback_t	Function pointer to the code executed when the timer expires.
cb_arg	void *	Pointer to data passed to the callback function. Can be NULL.
mode	ca_sw_timer_mode_t	Determines if the timer repeats (CA_TIMER_PERIODIC) or runs once (CA_TIMER_ONESHOT).
state	ca_sw_timer_state_t	Current operational state (e.g., running, stopped). Managed by the RTOS kernel.
active	u8	Flag indicating if the timer slot is allocated (1) or available (0).

Note:
The structure should be treated as opaque by the application. Always initialize the struct to zero before use. The RTOS kernel manages the timing logic; manual modification of 'remaining_ms' or 'state' will lead to undefined behavior.

Uso:
Use this type to create non-blocking delays or periodic background tasks. It is typically passed to timer management functions to register, start, or stop the timer instance.

Esempio:

```
void my_callback(void *arg) { /* Task logic here */ }

ca_sw_timer_t my_timer = {0};
my_timer.period_ms = 1000;
my_timer.cb = my_callback;
my_timer.mode = CA_TIMER_PERIODIC;
ca_timer_start(&my_timer);
```

ca_syslog_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:126:130

```
typedef struct {
ca_ipv4_t server_ip;   /* syslog server IPv4 */
u16     server_port; /* syslog UDP port (0 = 514 default) */
u8      facility;    /* syslog facility (0-23, 1=user) */
} ca_syslog_cfg_t;
```

Configuration structure used to define the destination and protocol parameters for the caOS system logging service.

Membri:

Nome	Tipo	Descrizione
server_ip	ca_ipv4_t	The IPv4 address of the remote syslog server. Must be a valid network-byte-order address.
server_port	u16	The UDP port number for the syslog server. Set to 0 to automatically use the standard syslog port 514.
facility	u8	The syslog facility code (0-23). Defines the type of program logging the message. Use 1 for general user-level messages.

Note:
This structure is typically passed by value or pointer to the system initialization routines. It does not require dynamic allocation; it is usually declared as a static configuration object in the application layer. Ensure the IP address is correctly formatted before passing to the network stack.

Uso:
Use this structure when configuring the system logging subsystem during the board initialization phase to enable remote log forwarding over UDP.

Esempio:

```
ca_syslog_cfg_t syslog_cfg = { .server_ip = {192, 168, 1, 50}, .server_port =
    514, .facility = 1 };
```

---

ca_task_fn_t

Tipo: Callback
File: caos/inc/scheduler.h:139:139

```
typedef u32 (*ca_task_fn_t)(u32 idx, u32 p1)
```

A function pointer type defining the entry point for a task in the caOS scheduler.

Membri:

Nome	Tipo	Descrizione
idx	u32	The unique index or ID assigned to the task instance. Used to identify which task is currently executing if multiple tasks share the same function.
p1	u32	A user-defined parameter passed to the task during creation. Typically used for configuration data or pointers to task-specific structures.

Note:
The function must be non-blocking and should ideally return 0 upon successful execution. It is invoked by the caOS scheduler context switch mechanism. Ensure the function is re-entrant if the task logic accesses shared resources.

Uso:
Used when defining the main logic of a task. You pass a pointer to a function matching this signature to the task creation API to register the task with the scheduler.

Esempio:

```
u32 my_task_logic(u32 idx, u32 p1) {
    // Task logic goes here
    return 0;
}

// Usage in task creation
ca_task_create(my_task_logic, 0, 1024, 1, NULL);
```

`ca_task_handle_t`

Tipo: simple
File: `caos/inc/scheduler.h:254:254`

```
typedef u32 ca_task_handle_t
```

An opaque identifier used by the kernel to uniquely reference and manage a specific task within the system.

Membri:

Nome	Tipo	Descrizione
`ca_task_handle_t`	`u32`	A numeric handle representing a task. It is used as an input parameter for task control functions like suspension, resumption, or priority modification.

Note:
The handle is typically obtained via ca_os_self_handle() for the current task or returned by task creation routines. It is managed by the scheduler; users should treat it as an opaque value and never attempt to modify its contents or perform arithmetic on it.

Uso:
Use this type whenever you need to perform operations on a specific task, such as changing its priority, suspending it, or waking it up from a blocked state.

Esempio:

```
#include "caos/inc/scheduler.h"

void task_control_example(void) {
    /* Get the handle of the currently running task */
    ca_task_handle_t my_handle = ca_os_self_handle();

    /* Suspend the current task */
    ca_os_suspend_handle(my_handle);

    /* Resume the task later */
    ca_os_resume_handle(my_handle);

    /* Change the priority of the task */
    ca_os_set_priority_handle(my_handle, 10);
}
```

ca_task_list_t

Tipo: Struttura
File: caos/inc/scheduler.h:235:240

```
typedef struct {
ca_thread_context_t **items;  /**< Pointer buffer */
u32 size;                     /**< Number of active elements */
u32 capacity;                 /**< Maximum capacity */
bool good;                    /**< Last operation validity flag */
} ca_task_list_t;
```

A dynamic container structure used by the scheduler to manage a list of task control blocks (ca_thread_context_t).

Membri:

Nome	Tipo	Descrizione
items	ca_thread_context_t **	A pointer to an array of pointers, where each pointer references a task's context. Must be allocated with sufficient memory to hold 'capacity' elements.
size	u32	The current number of tasks stored in the list. Must always be less than or equal to 'capacity'.
capacity	u32	The maximum number of tasks the list can hold. Defines the size of the memory buffer pointed to by 'items'.
good	bool	A status flag indicating if the last operation on the list was successful. True if successful, false if an error (e.g., overflow) occurred.

Note:
The structure itself does not manage the memory for the 'items' buffer; the user or the system allocator must provide a buffer of size (capacity * sizeof(ca_thread_context_t*)). The 'good' flag is updated by caOS internal functions to signal if an insertion or removal was valid.

Uso:
Used primarily by the scheduler to maintain queues of ready or blocked tasks. You will encounter this when inspecting the internal state of the scheduler or when implementing custom task management logic that requires grouping tasks.

Esempio:

```
ca_thread_context_t *task_buffer[10];
ca_task_list_t my_task_list = {
    .items = task_buffer,
    .size = 0,
    .capacity = 10,
    .good = true
};

// The list is now ready to be passed to internal caOS scheduler functions
// that accept a pointer to a ca_task_list_t structure.
```

ca_tcp_close_t

Tipo: Callback
File: caos/net/inc/tcp_service.h:38:38

```
typedef void (*ca_tcp_close_t)(u8 handle);     /* called on close/error */
```

A callback function pointer triggered by the TCP stack when a connection is closed or encounters a fatal error.

Membri:

Nome	Tipo	Descrizione
handle	u8	The unique identifier of the TCP connection that has been closed. Must be a valid handle previously opened by the stack.

Note:
This callback is executed within the context of the TCP service task. It is intended for cleanup operations, such as freeing application-level buffers or notifying other tasks. Do not perform blocking operations or long-running tasks inside this callback to avoid stalling the network stack.

Uso:
Used when registering a TCP service or connection configuration. Assign this function pointer to the 'on_close' field of a connection structure to handle asynchronous connection termination events.

Esempio:

```
void my_tcp_cleanup(u8 handle) {
    // Perform cleanup for the specific connection handle
    printf("Connection %d closed or failed.\n", handle);
}

// Usage in a configuration struct
ca_tcp_config_t config = {
    .on_close = my_tcp_cleanup,
    // ... other fields
};
```

---

ca_tcp_conn_t

Tipo: Callback
File: caos/net/inc/tcp_service.h:37:37

```
typedef void (*ca_tcp_conn_t)(u8 handle);     /* called when ESTABLISHED */
```

A callback function pointer triggered by the TCP stack when a new connection is successfully established.

Membri:

Nome	Tipo	Descrizione
handle	u8	The unique identifier (index) assigned to the new TCP connection. Must be used in subsequent API calls to identify this specific stream.

Note:

This callback is executed within the context of the TCP service task. It must be non-blocking and should not perform heavy processing. The user is responsible for storing the handle if they intend to send or receive data on this connection later.

Uso:
Used during the initialization of a TCP server or client to notify the application layer that the three-way handshake is complete and the socket is ready for data transmission.

Esempio:

```
void my_connection_handler(u8 handle) {
    printf("Connection established with handle: %d\n", handle);
}

// Registering the callback during service setup
ca_tcp_init(my_connection_handler);
```

---

ca_tcp_connect_cfg_t

Tipo: Struttura
File: caos/net/inc/tcp_service.h:43:53

```
typedef struct {
ipv4_t          remote_ip;
u16             remote_port;
ipv4_t          local_ip;
mac_t           local_mac;
u32             arp_timeout_ms;     /* 0     TCP_ARP_TIMEOUT_MS default */
u32             connect_timeout_ms; /* 0     TCP_CONNECT_TIMEOUT_MS default */
ca_tcp_rx_t     on_rx;              /* NULL = blocking ca_tcp_recv() mode */
ca_tcp_conn_t   on_connected;       /* NULL = blocking ca_tcp_connect() */
ca_tcp_close_t  on_closed;
} ca_tcp_connect_cfg_t;
```

Configuration structure used to define parameters and callback handlers for establishing a TCP connection.

Membri:

Nome	Tipo	Descrizione
remote_ip	ca_ipv4_t	The destination IPv4 address. Must be a valid network-order address.
remote_port	u16	The destination TCP port number.
local_ip	ca_ipv4_t	The local IPv4 address to bind to. Use 0.0.0.0 for default interface.
local_mac	ca_mac_t	The local MAC address associated with the interface.
arp_timeout_ms	u32	Time to wait for ARP resolution. Set to 0 to use the system default.
connect_timeout_ms	u32	Time to wait for the TCP handshake to complete. Set to 0 to use the system default.
on_rx	ca_tcp_rx_t	Callback function for incoming data. If NULL, the socket operates in blocking mode.
on_connected	ca_tcp_conn_t	Callback triggered upon successful connection. If NULL, the connect function blocks until completion.
on_closed	ca_tcp_close_t	Callback triggered when the connection is closed by either party.

Note:
The structure is typically allocated on the stack before calling the connection function. If callbacks are provided, the socket operates asynchronously; otherwise, it operates synchronously (blocking). Ensure all fields are zero-initialized if you intend to use default values for timeouts.

Uso:
Used as an argument in the TCP connection API to specify target parameters and event handling behavior. It is essential for non-blocking network applications where the CPU must perform other tasks while waiting for network events.

Esempio:

```
ca_tcp_connect_cfg_t cfg = {0};
cfg.remote_ip = ip_addr_make(192, 168, 1, 100);
cfg.remote_port = 80;
cfg.on_rx = my_rx_callback;
cfg.on_closed = my_close_callback;
ca_tcp_connect(socket_handle, &cfg);
```

---

ca_tcp_frame_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:135:145

```
typedef struct {
u16     src_port;  /* source port big-endian */
u16     dst_port;  /* destination port big-endian */
u32     seq;       /* sequence number big-endian */
u32     ack_seq;   /* acknowledgement number big-endian */
u8      data_off;  /* [7:4]=header length in 32-bit words, [3:0]=reserved
    */
u8      flags;     /* TCP_FLAG_* */
u16     window;    /* receive window big-endian */
u16     checksum;  /* pseudo-header checksum big-endian */
u16     urg_ptr;   /* urgent pointer big-endian (unused) */
} __attribute__((packed)) ca_tcp_frame_t;
```

Represents the raw TCP header structure used for packet parsing and construction in the caOS network stack.

Membri:

Nome	Tipo	Descrizione
`src_port`	`u16`	Source port number in network byte order (big-endian). Must be converted from host byte order using htons() if necessary.
`dst_port`	`u16`	Destination port number in network byte order (big-endian).
`seq`	`u32`	TCP sequence number in network byte order. Used to track the order of data segments.
`ack_seq`	`u32`	Acknowledgment number in network byte order. Indicates the next sequence number expected.
`data_off`	`u8`	High 4 bits represent the header length in 32-bit words. Low 4 bits are reserved and should be 0.
`flags`	`u8`	TCP control flags (e.g., SYN, ACK, FIN). Use defined TCP_FLAG_* constants.
`window`	`u16`	Receive window size in network byte order, indicating available buffer space.
`checksum`	`u16`	16-bit one's complement of the one's complement sum of the TCP header and data, plus a pseudo-header.
`urg_ptr`	`u16`	Urgent pointer field, typically unused in standard caOS implementations.

Note:
The struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, matching the exact wire format of a TCP header. Always ensure multi-byte fields are in big-endian format before transmission.

Uso:
Used when manually crafting TCP packets or parsing incoming raw network buffers within the caOS network layer. It is typically cast onto a pointer of a received network buffer.

Esempio:

```
ca_tcp_frame_t *tcp_hdr = (ca_tcp_frame_t *)(buffer + ip_header_len);
tcp_hdr->src_port = htons(80);
tcp_hdr->dst_port = htons(1234);
tcp_hdr->flags = TCP_FLAG_ACK | TCP_FLAG_PSH;
tcp_hdr->seq = htonl(current_seq_num);
```

`ca_tcp_listen_cfg_t`

Tipo: Struttura
File: `caos/net/inc/tcp_service.h:113:120`

```
typedef struct {
u16            local_port;
ipv4_t         local_ip;
mac_t          local_mac;
ca_tcp_conn_t  on_accept;   /* NULL = blocking ca_tcp_accept() mode */
ca_tcp_rx_t    on_rx;       /* NULL = blocking ca_tcp_recv() on data
   conn */
```

```
ca_tcp_close_t on_closed;
} ca_tcp_listen_cfg_t;
```

Configuration structure used to define the parameters and event callbacks for a TCP listening socket.

Membri:

Nome	Tipo	Descrizione
`local_port`	`u16`	The TCP port number to bind the listener to. Must be a valid non-zero port.
`local_ip`	`ca_ipv4_t`	The local IPv4 address to bind. Use 0.0.0.0 to listen on all available network interfaces.
`local_mac`	`ca_mac_t`	The MAC address associated with the interface. Usually retrieved from the network stack configuration.
`on_accept`	`ca_tcp_conn_t`	Callback function triggered when a new connection is established. If NULL, the system defaults to blocking mode.
`on_rx`	`ca_tcp_rx_t`	Callback function triggered when data is received on the connection. If NULL, the system defaults to blocking mode.
`on_closed`	`ca_tcp_close_t`	Callback function triggered when the connection is closed by either party.

Note:
This structure is typically passed by value or pointer to the TCP initialization API. The user is responsible for allocating this struct, usually on the stack or as a static global. Ensure all callback pointers are either valid functions or explicitly set to NULL to avoid undefined behavior.

Uso:
Use this struct when setting up a TCP server listener. It defines the network identity of the server and the event-driven behavior for handling incoming connections and data streams.

Esempio:

```
ca_tcp_listen_cfg_t cfg = {0};
cfg.local_port = 8080;
cfg.local_ip = IPV4_ADDR(192, 168, 1, 10);
cfg.on_accept = my_accept_callback;
cfg.on_rx = my_rx_callback;
cfg.on_closed = my_close_callback;
ca_tcp_listen(&cfg);
```

`ca_tcp_rx_raw_t`

Tipo: Callback
File: `caos/net/inc/net_proto.h:222:222`

```
typedef void (*ca_tcp_rx_raw_t)(u16 buf_idx)
```

A callback function type used by the TCP stack to notify the application when raw data has been received.

Membri:

Nome	Tipo	Descrizione
`buf_idx`	`u16`	An index representing the internal network buffer containing the received TCP payload. This index is used to retrieve or process the data.

Note:
This callback is executed within the context of the network stack. It must be kept short and efficient to avoid blocking network processing. The buffer associated with buf_idx is typically managed by the stack; ensure you call the appropriate buffer release function if the stack expects the user to free it.

Uso:
Used when registering a TCP listener or connection handler via the network stack. It allows the application to react immediately to incoming TCP segments.

Esempio:

```c
void my_tcp_rx_handler(u16 buf_idx) {
    /* Retrieve the pointer to the received data buffer */
    void *data = ca_net_buf_ptr(buf_idx);

    /* Process the data here */
    ca_printf("Received TCP data at index %d\n", buf_idx);

    /* Release the buffer back to the network pool after processing */
    ca_net_buf_free(buf_idx);
}

/* Usage in initialization */
void init_network(void) {
    /* Register the callback to handle incoming raw TCP data */
    ca_net_register(my_tcp_rx_handler);
}
```

---

ca_tcp_rx_t

Tipo: Callback
File: caos/net/inc/tcp_service.h:36:36

```c
typedef void (*ca_tcp_rx_t)(u8 handle, const u8 *data, u16 len)
```

A callback function type used to handle incoming TCP data packets received by the caOS network stack.

Membri:

Nome	Tipo	Descrizione
handle	u8	The unique identifier of the TCP connection that received the data. Must be a valid handle returned by a previous connection request.
data	const u8 *	Pointer to the buffer containing the received payload. This memory is managed by the stack and is only valid for the duration of the callback.
len	u16	The number of bytes available in the data buffer. Must be checked before accessing the buffer to prevent out-of-bounds reads.

Note:
This callback is executed within the context of the network task. It must be non-blocking and should not perform heavy processing. The data pointer is read-only; modifying it will corrupt the internal network buffer. The user does not allocate or free the data buffer.

Uso:

Used when registering a TCP service or connection. You assign a function matching this signature to the rx_callback field of a TCP configuration structure to process incoming network traffic.

Esempio:

```
void my_tcp_handler(u8 handle, const u8 *data, u16 len) {
    if (len > 0) {
        // Process incoming data here
        process_packet(data, len);
    }
}

// Usage in configuration
ca_tcp_config_t config = {
    .rx_callback = my_tcp_handler,
    // ... other fields
};
```

---

ca_temp_alarm_cb_t

Tipo: Callback
File: caos/drivers/inc/temp_sensor.h:22:22

```
typedef void (*ca_temp_alarm_cb_t)(bool hot);    /* called from the DTS
    interrupt */
```

A callback function type triggered by the internal temperature sensor (DTS) interrupt when a temperature threshold is crossed.

Membri:

Nome	Tipo	Descrizione
hot	bool	Indicates the alarm state. 'true' means the temperature has exceeded the high threshold; 'false' means it has returned to a safe level.

Note:
This callback is executed directly from the DTS interrupt service routine (ISR). It must be extremely fast, non-blocking, and must not perform any operations that require waiting (like mutex locks or heavy processing). It is registered via the ca_temp_set_alarm function.

Uso:
Use this to implement safety shutdowns or cooling fan control when the MCU temperature exceeds safe operating limits.

Esempio:

```
/* Callback implementation */
void my_temp_handler(bool hot) {
    if (hot) {
        /* Trigger emergency cooling or system shutdown */
        ca_led_on(0);
    } else {
        ca_led_off(0);
    }
}

/* Registration */
void setup_temp_monitoring(void) {
    /* Register the callback to the temperature sensor driver */
```

```
    ca_temp_set_alarm(my_temp_handler);
}
```

---

ca_tftp_cfg_t

Tipo: Struttura
File: caos/net/inc/tftp_service.h:88:97

```
typedef struct {
ipv4_t      server_ip;
const char *filename;
mac_t       local_mac;
ipv4_t      local_ip;
u16         local_port;         /* 0 = auto ephemeral */
u32         arp_timeout_ms;     /* 0 = 2000 ms */
u32         block_timeout_ms;   /* 0 = TFTP_BLOCK_TIMEOUT_MS */
u8          retry_n;            /* 0 = TFTP_RETRY_N */
} ca_tftp_cfg_t;
```

Configuration structure used to define the parameters for a TFTP client transfer session.

Membri:

Nome	Tipo	Descrizione
server_ip	ca_ipv4_t	The IPv4 address of the remote TFTP server. Must be a valid network-byte-order address.
filename	const char *	Pointer to a null-terminated string representing the path of the file to request or send.
local_mac	ca_mac_t	The MAC address of the local network interface to be used for the transfer.
local_ip	ca_ipv4_t	The local IPv4 address assigned to the interface.
local_port	u16	The local UDP port. Set to 0 to allow the stack to assign an automatic ephemeral port.
arp_timeout_ms	u32	Timeout in milliseconds for ARP resolution. Set to 0 to use the default 2000ms.
block_timeout_ms	u32	Timeout in milliseconds for waiting for a data block. Set to 0 to use the system default.
retry_n	u8	Maximum number of retries before aborting the transfer. Set to 0 to use the system default.

Note:
The structure is passed by value or reference to TFTP client functions. The caller is responsible for ensuring the 'filename' string remains valid for the duration of the transfer. Fields set to 0 trigger the use of internal caOS default values.

Uso:
Use this structure to initialize a TFTP transfer session. It is typically passed as an argument to the client-side TFTP initiation functions to configure network routing and timing parameters.

Esempio:

```
ca_tftp_cfg_t tftp_cfg = { .server_ip = {192, 168, 1, 10}, .filename = "firmware
    .bin", .local_mac = {0x00, 0x11, 0x22, 0x33, 0x44, 0x55}, .local_ip = {192,
    168, 1, 50}, .local_port = 0, .arp_timeout_ms = 0, .block_timeout_ms = 5000,
     .retry_n = 3 };
```

---

ca_tftp_err_t

Tipo: Struttura
File: caos/net/inc/tftp_service.h:74:77

```
typedef struct {
u16  code;      /* TFTP_ERR_*, or CA_TFTP_NO_ERROR */
char msg[48];   /* its text, printable ASCII */
} ca_tftp_err_t;
```

A structure used to report TFTP protocol errors, containing a numeric error code and a descriptive message string.

Membri:

Nome	Tipo	Descrizione
code	u16	The specific TFTP error code (e.g., TFTP_ERR_FILE_NOT_FOUND) or CA_TFTP_NO_ERROR if the operation succeeded.
msg	char[48]	A human-readable string describing the error. Must be null-terminated and fit within 48 bytes.

Note:
This struct is typically populated by the caOS TFTP service layer when a transfer fails. It is stack-allocated by the caller or the service handler. Ensure the 'msg' buffer is not overflowed if manually constructing this struct.

Uso:
Used as a return type or output parameter in TFTP client functions like ca_tftp_get or ca_tftp_put to provide diagnostic information when a network transfer fails.

Esempio:

```
ca_tftp_err_t err;
/* Attempt to retrieve a file via TFTP */
/* Assuming a hypothetical buffer and address setup */
err = ca_tftp_get(remote_ip, "config.bin", local_buffer);

if (err.code != CA_TFTP_NO_ERROR) {
    /* Log the error message to the system console */
    ca_printf("TFTP Error %d: %s\n", err.code, err.msg);
}
```

---

ca_tftp_rx_block_t

Tipo: Callback
File: caos/net/inc/tftp_service.h:80:80

```
typedef bool (*ca_tftp_rx_block_t)(u16 block_num,
```

A callback function type triggered by the TFTP service whenever a new data block is successfully received.

Membri:

Nome	Tipo	Descrizione
block_num	u16	The sequence number of the TFTP block currently being received. Starts at 1 for the first data block.
data	const u8 *	Pointer to the buffer containing the raw payload of the received block.
len	u16	The number of bytes contained in the data buffer. Valid values are 0 to 512.

Note:
The callback must return true to acknowledge the block and continue the transfer, or false to abort the transfer (e.g., if a write error occurs). The memory pointed to by 'data' is only valid for the duration of the callback execution; do not store the pointer for later use.

Uso:
Used when configuring a TFTP server or client instance to process incoming file data. You assign a function matching this signature to the 'rx_callback' field in the TFTP configuration structure before starting the service.

Esempio:

```
static bool my_tftp_handler(u16 block_num, const u8 *data, u16 len) { if (len > 0) { flash_write_page(block_num, data, len); return true; } return false; }
// Usage in config: .rx_callback = my_tftp_handler;
```

---

ca_tftp_srv_cfg_t

Tipo: Struttura
File: caos/net/inc/tftp_service.h:140:147

```
typedef struct {
ca_mac_t    local_mac;
ca_ipv4_t   local_ip;           /* 0 = the current address of the stack */
u16         port;               /* listening port, 0 = TFTP_PORT */
u32         block_timeout_ms;   /* 0 = TFTP_BLOCK_TIMEOUT_MS */
u8          retry_n;            /* 0 = TFTP_RETRY_N */
ca_tftp_err_t *err;             /* NULL, or filled with the peer's ERROR packet */
} ca_tftp_srv_cfg_t;
```

Configuration structure for initializing and managing a TFTP server instance in caOS.

Membri:

Nome	Tipo	Descrizione
local_mac	ca_mac_t	The MAC address to bind the TFTP server to. If zero, the stack's default interface is used.
local_ip	ca_ipv4_t	The IPv4 address to bind the TFTP server to. Set to 0 to use the current stack IP address.
port	u16	UDP port for listening. Set to 0 to use the default TFTP port (69).
block_timeout_ms	u32	Timeout in milliseconds for waiting on data blocks. Set to 0 to use the system default.
retry_n	u8	Number of retries before aborting a transfer. Set to 0 to use the system default.
err	ca_tftp_err_t *	Pointer to a structure that will be populated if the peer sends a TFTP ERROR packet. Can be NULL.

Note:
This structure is passed to the TFTP service initialization functions. The user is responsible for allocating this struct (usually on the stack or as a global). The fields set to 0 act as 'use default' flags, allowing for easy partial configuration.

Uso:
Use this structure when setting up a TFTP server instance to define network binding and timeout behavior before calling the service initialization functions.

Esempio:

```
ca_tftp_srv_cfg_t tftp_cfg;
ca_tftp_err_t last_err;

/* Initialize configuration with defaults */
ca_memzero(&tftp_cfg, sizeof(tftp_cfg));
tftp_cfg.port = 69;
tftp_cfg.err = &last_err;

/* Pass the configuration to the TFTP service initialization */
ca_tftp_service_init(&tftp_cfg);
```

`ca_tftp_wrq_t`

Tipo: Callback
File: `caos/net/inc/tftp_service.h:154:154`

```
typedef u16 (*ca_tftp_wrq_t)(const char *filename, ca_ipv4_t client,
    void *arg)
```

Callback function type used to handle incoming TFTP Write Request (WRQ) packets.

Membri:

Nome	Tipo	Descrizione
`filename`	`const char *`	The name of the file requested by the client to be written to the server.
`client`	`ca_ipv4_t`	The IPv4 address of the remote client initiating the write request.
`arg`	`void *`	User-defined context pointer passed during the TFTP service registration.

Note:
The function must return a 16-bit status code. A return value of 0 typically indicates success, while non-zero values represent specific TFTP error codes. This callback is executed within the context of the TFTP service thread; therefore, it should be non-blocking and efficient to avoid stalling network processing.

Uso:
Used when configuring the TFTP service to define custom logic for handling file uploads. You implement this function to validate the filename or check permissions before the server accepts the incoming data stream.

Esempio:

```
u16 my_tftp_wrq_handler(const char *filename, ca_ipv4_t client, void *arg) {
    /* Check if the filename is allowed */
    if (ca_strcmp(filename, "config.bin") != 0) {
        return 1; /* Return TFTP error code 1: File not found */
    }
```

```
    /* Log the request using system printf */
    ca_printf("TFTP WRQ received for file: %s\n", filename);
    return 0; /* Success */
}
```

---

ca_thread_context_t

Tipo: Struttura
File: caos/inc/scheduler.h:152:205

```
typedef struct __attribute__((packed, aligned(4))) ca_thread_context {
/* Hardware context (Cortex-M4) */
u32 digest;             /* 0 0xCACAFEFE*/
/* Registers saved automatically by hardware (read from stack) */
u32 r[13];              /**< 4+52 R0-R12 */
u32 lr;                 /**< 56+4 Link Register */
u32 pc;                 /**< 60+4 Program Counter */
u32 xpsr;               /**< 64+4 xPSR */
u32 psp;                /**< 68+4 Process Stack Pointer */
/* Task metadata */
u32 stack_start;        /**< 72+4 Start of stack area */
u32 stack_end;          /**< 76+4 End of stack area (with guard) */
/* Scheduling */
u16 index;              /**< 80+2 Index in taskList array */
u16 priority;           /**< 82+2 EFFECTIVE priority (the scheduler's
   weight):
prio_base raised by priority inheritance */
u16 num_alloc;          /**< 84+2 Number of allocated heap blocks */
volatile u16 status;    /**< 86+2 Task status (ISR-shared: volatile
prevents compiler reordering/caching) */
/* Statistics + Notification */
volatile u32 notify_value; /**< 88+4 Task notification value (ISR-shared
   ) */
u32 nswitch;            /**< 92+4 Number of context switches */
u32 running;            /**< 96+4 Total task lifetime */
u32 sleep;              /**< 100+4 remaining clocks if in sleep */
void *wait_list;        /**< 104+4 ca_wait_queue_t the task is linked in
   , NULL if none
(was 'blocked', a refresh counter no one used) */
u32 result;             /**< 108+4 Task return value */

/* Debug / Stack monitoring */
struct ca_thread_context *next_task_wait;  /**< 112+4 the next task in
   wait state */
/* Emergency handler (fault-safe) */
ca_task_fn_t thread_exec;     /**< 116+4 the thread entry function */
u32 p1;                 /**< 120+4 entry parameter */
u32 emerg_param;        /**< 124+4 parameter for emergency handler */
ca_emergency_fn_t emergency_exec;  /**< 128+4  the function for
   emergency management*/
u32 runtime_enter;      /**< 132+4 last CYCCNT task entry */
u32 runtime_peak_max;   /**< 136+4 maximum duration (WCET) in clock
   cycles */
u32 runtime_total;      /**< 140+4 total cumulative runtime in clock
   cycles */
u32 runtime_wdt;        /**< 144+4 WDT threshold in clock cycles (0=
   disabled) */
```

```
40 u16 n_assert;            /**< 148+2 number of asserts for this thread  */
41 u16 n_restart;           /**< 150+2 number of restarts for this thread */
42 u16 n_memfault;          /**< 152+2 number of memfaults for this thread
   */
43 u16 prio_base;           /**< 154+2 priority given at creation /
   set_priority */
44 u16 stack_usage_pct;     /**< 156+2 0-1000 (0.0%-100.0%) */
45 u16 fault_type;          /**< 158+2 recovery policy: CA_ONLY_ASSERT/
   RESTART/EMERGENCY */
46
47 /* Priority inheritance (sync.c): effective priority = max(prio_base,
   the
48 * waiters of every mutex in pi_held), propagated along pi_wait owners */
49 struct ca_mutex_s *pi_held; /**< 160+4 mutexes this task owns (list) */
50 struct ca_mutex_s *pi_wait; /**< 164+4 mutex this task is blocked on */
51
52 char name[TASK_NAME_LEN];          /**< 168+12 thread name*/
53 /* 180 size END*/
54 } ca_thread_context_t;
```

Represents the complete execution state, metadata, and scheduling information for a single task in the caOS RTOS.

Membri:

Nome	Tipo	Descrizione
`digest`	`u32`	Magic number 0xCACAFEFE used for stack integrity validation.
`r[13], lr, pc, xpsr`	`u32[]`	Hardware registers saved during context switches to allow task resumption.
`psp`	`u32`	Process Stack Pointer; tracks the current stack location for this specific task.
`stack_start, stack_end`	`u32`	Memory boundaries of the task stack; used for overflow detection.
`priority`	`u16`	The current effective priority used by the scheduler, potentially boosted by priority inheritance.
`status`	`u16`	Current task state (e.g., READY, BLOCKED, RUNNING). Marked volatile as it is modified by ISRs.
`notify_value`	`u32`	A 32-bit value used for inter-task signaling and synchronization.
`thread_exec`	`ca_task_fn_t`	Pointer to the function that serves as the entry point for the task.
`name`	`char[]`	Human-readable identifier for the task, useful for debugging.

Note:
This structure is managed internally by the caOS kernel. Users should never manually modify these fields. The structure is packed and aligned to 4 bytes to match the Cortex-M4 stack frame requirements. Memory for this struct is typically allocated by the kernel during task creation.

Uso:
Used by the kernel scheduler to manage multitasking. While you rarely interact with this struct directly, it is referenced when inspecting task lists, debugging stack usage, or monitoring task statistics via kernel diagnostic tools.

Esempio:

```c
/* Example of accessing task metadata for debugging purposes */
void print_task_info(ca_thread_context_t *task) {
    if (task != NULL) {
        printf("Task Name: %s\n", task->name);
        printf("Current Priority: %u\n", task->priority);
        printf("Stack Usage: %u.%u%%\n", task->stack_usage_pct / 10, task->
    stack_usage_pct % 10);
    }
}
```

---

ca_tick_speed_t

Tipo: Enumerazione
File: caos/inc/systick.h:33:44

```c
typedef enum __attribute__((packed)) tag_speed {
CA_TICK_SPEED_100US = 100,
CA_TICK_SPEED_200US = 200,
CA_TICK_SPEED_250US = 250,
CA_TICK_SPEED_400US = 400,
CA_TICK_SPEED_500US = 500,
CA_TICK_SPEED_1MS = 1000,
CA_TICK_SPEED_2MS = 2000,
CA_TICK_SPEED_4MS = 4000,
CA_TICK_SPEED_5MS = 5000,
CA_TICK_SPEED_10MS = 10000,
} ca_tick_speed_t;
```

An enumeration defining the duration of a single system tick in microseconds, used to configure the RTOS heartbeat frequency.

Membri:

Nome	Tipo	Descrizione
CA_TICK_SPEED_100US to CA_TICK_SPEED_10MS	enum constant	Represents the tick period in microsecond values result in lower CPU overhead bu timing resolution for tasks and delays.

Note:
This enum is used to configure the hardware timer responsible for the RTOS system tick. It must be set during the system initialization phase before the scheduler starts. The values are packed to save memory, and the integer value corresponds directly to the period in microseconds.

Uso:
Used as an argument when initializing the system clock or RTOS kernel to define the base time unit for all kernel-level timing operations like delays and timeouts.

Esempio:

```c
ca_tick_speed_t my_tick_rate = CA_TICK_SPEED_1MS;

void system_init(void) {
    /* Configure the system tick to trigger every 1ms */
    caos_systick_init(my_tick_rate);
}
```

---

ca_timer_callback_t

Tipo: Callback
File: caos/inc/sw_timer.h:50:50

```
typedef void (*ca_timer_callback_t)(void *arg)
```

A function pointer type used to define the callback function executed when a software timer expires.

Membri:

Nome	Tipo	Descrizione
arg	void *	A user-defined pointer passed to the callback function. It allows the callback to access context-specific data (e.g., a struct or a peripheral handle). Must be a valid memory address or NULL.

Note:
The callback function is executed within the context of the caOS timer service task. Therefore, the callback must be kept short and efficient. Blocking operations, such as infinite loops or long delays, must be avoided to prevent system-wide timing jitter or starvation of other tasks.

Uso:
Used when creating a software timer via the caOS timer API. You define a function matching this signature and pass its address during timer initialization or configuration to handle periodic or one-shot events.

Esempio:

```
void my_timer_handler(void *arg) { uint32_t *counter = (uint32_t *)arg; (*
    counter)++; } ... ca_timer_t my_timer; uint32_t event_count = 0;
    ca_timer_init(&my_timer, my_timer_handler, &event_count, 100,
    CA_TIMER_PERIODIC);
```

---

ca_timer_cb_t

Tipo: Callback
File: caos/drivers/inc/timer.h:39:39

```
typedef void (*ca_timer_cb_t)(void)
```

A function pointer type used to define the callback routine executed when a caOS software timer expires.

Membri:

Nome	Tipo	Descrizione
ca_timer_cb_t	void (*)(void)	A pointer to a function that takes no arguments and returns nothing. This function is invoked by the system timer task upon timeout.

Note:
The callback function runs in the context of the timer task or an ISR depending on the RTOS configuration. It must be kept short and non-blocking to avoid starving other system tasks. Do not perform heavy processing or infinite loops inside this function.

Uso:

Used when registering a software timer via the caOS timer API. Assign a function name to a variable of this type and pass it to the timer initialization function to define the action taken upon expiration.

Esempio:

```
void my_timer_handler(void) { /* Toggle an LED or set a flag */ }

/* Usage in timer setup */
ca_timer_cb_t my_callback = my_timer_handler;
ca_timer_create(my_callback, 1000);
```

---

ca_timer_ic_cb_t

Tipo: Callback
File: caos/drivers/inc/timer.h:66:66

```
typedef void (*ca_timer_ic_cb_t)(u32 ticks)
```

A callback function type used to handle timer input capture events in caOS.

Membri:

Nome	Tipo	Descrizione
ticks	u32	The timer counter value captured at the moment the event occurred. Represents the timestamp of the input signal.

Note:
This callback is executed within the context of the timer interrupt service routine (ISR). Keep the implementation extremely short and avoid blocking operations, mutexes, or heavy processing. If complex logic is required, use the callback to signal a task (e.g., via ca_notify_give_isr) and process the data there.

Uso:
Used when configuring hardware timers for input capture mode. You pass a function pointer of this type to the ca_timer_capture_event function to register your custom logic to be triggered whenever the timer hardware detects an input signal edge.

Esempio:

```
void my_capture_handler(u32 ticks) {
    /* Signal a task that a capture event occurred */
    ca_notify_give_isr(capture_task_handle);
}

void setup_timer(void) {
    /* Register the callback for the timer capture event */
    ca_timer_capture_event(TIMER_ID, my_capture_handler);
}
```

---

ca_timer_ic_src_t

Tipo: Enumerazione
File: caos/drivers/inc/timer.h:58:62

```
typedef enum {
CA_TIMER_IC_PIN = 0,
CA_TIMER_IC_LSE,
CA_TIMER_IC_LSI
} ca_timer_ic_src_t;
```

Defines the input source for a hardware timer's input capture or clocking mechanism.

Membri:

Nome	Tipo	Descrizione
CA_TIMER_IC_PIN	enum value	Uses an external physical GPIO pin as the input source.
CA_TIMER_IC_LSE	enum value	Uses the Low Speed External (LSE) crystal oscillator as the input source.
CA_TIMER_IC_LSI	enum value	Uses the Low Speed Internal (LSI) RC oscillator as the input source.

Note:
This enum is used to configure the hardware timer peripheral. It does not require manual allocation as it is a simple enumeration passed by value to initialization functions. Ensure the selected source is physically available and enabled on the STM32 hardware before calling the initialization function.

Uso:
Used primarily in the ca_timer_init_capture function to specify which signal should trigger the capture event or drive the timer counter.

Esempio:

```
#include "caos/drivers/inc/timer.h"

void setup_timer_capture(void) {
    /* Configure timer 2 to capture events from an external GPIO pin */
    /* The function ca_timer_init_capture takes the timer ID, the source, and a
    callback */
    ca_timer_init_capture(2, CA_TIMER_IC_PIN, NULL);

    /* Start the timer to begin monitoring the input source */
    ca_timer_start(2);
}
```

---

ca_timer_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/timer.h:41:48

```
typedef enum {
TIMER_MODE_PERIODIC = 0,
TIMER_MODE_ONESHOT,
TIMER_MODE_COUNTER,
TIMER_MODE_ENCODER,
TIMER_MODE_COUNTER_IRQ,  /* down counter su clock ETR, IRQ ogni preset
    impulsi */
TIMER_MODE_PWM,          /* output PWM, fino a 4 canali per timer */
} ca_timer_mode_t;
```

Defines the operational behavior of a hardware timer peripheral in caOS.

Membri:

Nome	Tipo	Descrizione
CA_TIMER_MODE_PERIODIC	enum constant	Timer triggers an interrupt or event at a fixed, repeating time interval.
CA_TIMER_MODE_ONESHOT	enum constant	Timer triggers once after a delay and then stops automatically.
TIMER_MODE_COUNTER	enum constant	Timer increments or decrements based on external clock pulses.
CA_TIMER_MODE_ENCODER	enum constant	Configures the timer to decode quadrature signals from a rotary encoder.
TIMER_MODE_COUNTER_IRQ	enum constant	Counts external ETR pulses and triggers an interrupt when a preset threshold is reached.
CA_TIMER_MODE_PWM	enum constant	Configures the timer to generate Pulse Width Modulation signals on up to 4 output channels.

Note:
This enum is used during the hardware initialization phase of a timer. It determines which internal STM32 registers are configured. Ensure the selected mode is physically supported by the specific timer instance (e.g., not all timers support PWM or Encoder modes).

Uso:
Pass this value to the timer configuration structure before calling the driver's initialization function to define the timer's functional role in your application.

Esempio:

```
ca_timer_config_t my_timer_cfg = { .mode = CA_TIMER_MODE_PWM, .period = 1000, .
    prescaler = 84 }; ca_timer_init(TIMER2, &my_timer_cfg);
```

---

ca_tls_config_t

Tipo: Struttura
File: caos/net/inc/tls.h:90:96

```
typedef struct {
const u8   *cert_der;
u32         cert_len;
const u8   *private_key;            /* 32 bytes, P-256 */
const char *alpn;                   /* e.g. "http/1.1", NULL = none */
u32         handshake_timeout_ms;   /* each read during the handshake */
} ca_tls_config_t;
```

Configuration structure for initializing a TLS connection, containing identity credentials and handshake parameters.

Membri:

Nome	Tipo	Descrizione
cert_der	const u8 *	Pointer to the device certificate in DER format. Must remain valid for the duration of the TLS session.
cert_len	u32	Length of the certificate in bytes.
private_key	const u8 *	Pointer to the 32-byte P-256 private key. Must be kept secure and valid during the session.
alpn	const char *	Application-Layer Protocol Negotiation string (e.g., "http/1.1"). Set to NULL if not required.
handshake_timeout_ms	u32	Timeout in milliseconds for each read operation during the TLS handshake process.

Note:
The structure does not own the memory pointed to by cert_der or private_key; the caller must ensure these buffers persist as long as the TLS connection is active. This struct is typically passed by value or reference to TLS initialization routines.

Uso:
Used to define the security identity and handshake behavior before initiating a secure connection via ca_tls_* functions.

Esempio:

```c
#include "caos/net/inc/tls.h"

void setup_secure_connection(void) {
    static const u8 my_cert[] = {0x30, 0x82, ...}; // DER data
    static const u8 my_key[] = {0x01, 0x02, ...};  // 32 bytes

    ca_tls_config_t tls_cfg = {
        .cert_der = my_cert,
        .cert_len = sizeof(my_cert),
        .private_key = my_key,
        .alpn = "http/1.1",
        .handshake_timeout_ms = 5000
    };

    /* Proceed to use tls_cfg with ca_tls_* functions to establish connection */
}
```

---

ca_tls_dir_t

Tipo: Struttura
File: `caos/net/inc/tls.h:99:104`

```c
typedef struct {
ca_aes_ctx_t aes;
u8           iv[12];
u64          seq;
u8           secret[32];            /* traffic secret, for KeyUpdate */
} ca_tls_dir_t;
```

Represents the cryptographic state (AES context, IV, sequence number, and secret) for one direction of a TLS connection.

Membri:

Nome	Tipo	Descrizione
`aes`	`ca_aes_ctx_t`	The AES context used for encryption or decryption operations.
`iv`	`u8[12]`	The Initialization Vector (IV) used for the current record, typically 12 bytes for AES-GCM.
`seq`	`u64`	The 64-bit sequence number used to prevent replay attacks; must be incremented for every record.
`secret`	`u8[32]`	The current traffic secret, used for key derivation during KeyUpdate procedures.

Note:
This struct is typically part of a larger TLS session object. It is not automatically managed by the OS; the application or the TLS stack must ensure it is zeroed out using ca_memzero before use and after the connection is closed to prevent sensitive data leakage.

Uso:
Used internally by the TLS stack to maintain the state of the encryption/decryption stream. You will encounter this when implementing custom TLS record processing or debugging low-level secure communication layers.

Esempio:

```
ca_tls_dir_t tls_dir;

/* Initialize the structure to ensure no garbage data is present */
ca_memzero(&tls_dir, sizeof(ca_tls_dir_t));

/* Setup the AES context within the TLS direction struct */
ca_aes_ctx_setup(&tls_dir.aes, /* key pointer */ NULL, 32);

/* Increment sequence number before sending a new record */
tls_dir.seq++;
```

---

ca_tls_io_t

Tipo: Struttura
File: caos/net/inc/tls.h:77:81

```
typedef struct {
i32  (*send)(void *io, const u8 *data, u32 len);
i32  (*recv)(void *io, u8 *buf, u32 len, u32 timeout_ms);
void  *io;
} ca_tls_io_t;
```

An abstraction layer (I/O interface) used by the TLS stack to perform read/write operations on custom transport mediums.

Membri:

Nome	Tipo	Descrizione
send	i32 (*)(void *io, const u8 *data, u32 len)	Function pointer to the custom send implementation. Must return the number of bytes sent or a negative value on error.
recv	i32 (*)(void *io, u8 *buf, u32 len, u32 timeout_ms)	Function pointer to the custom receive implementation. Must return the number of bytes received or a negative value on error.
io	void *	Opaque pointer to the underlying transport object (e.g., a socket handle or a stream pointer) passed as the first argument to send/recv.

Note:
The struct is typically allocated by the user and passed to TLS initialization functions. The user is responsible for ensuring the 'io' pointer remains valid for the entire duration of the TLS session. The callbacks must be thread-safe if the TLS session is accessed from multiple tasks.

Uso:
Used to decouple the TLS library from specific hardware or network drivers. You define this struct to wrap your specific communication channel (like a TCP socket or a UART stream) so the TLS stack can perform encrypted communication over it.

Esempio:

```
static i32 my_send(void *io, const u8 *data, u32 len) { /* Use ca_tcp_send or similar to transmit data */ return (i32)len; } static i32 my_recv(void *io, u8 *buf, u32 len, u32 timeout_ms) { /* Use ca_tcp_recv or similar to receive data */ return 0; } void setup_tls(void *my_socket) { ca_tls_io_t tls_io; tls_io.send = my_send; tls_io.recv = my_recv; tls_io.io = my_socket; /* Now pass tls_io to the TLS service initialization */ }
```

---

ca_tls_t

Tipo: Struttura
File: caos/net/inc/tls.h:106:126

```
typedef struct {
ca_tls_io_t              io;
const ca_tls_config_t   *cfg;
ca_sha256_ctx_t          transcript;
ca_tls_dir_t             rd;
ca_tls_dir_t             wr;
bool                     rd_encrypted;
bool                     wr_encrypted;
bool                     established;
bool                     closed;
u8                       alert;          /* last alert sent or received */

/* Application data received but not yet handed to ca_tls_read */
u32                      app_off;
u32                      app_len;

u8                       rx[TLS_RX_BUF_SIZE];
u8                       tx[TLS_TX_BUF_SIZE];
u8                       hs[TLS_HS_BUF_SIZE];
u32                      hs_len;
} ca_tls_t;
```

Represents the state and buffers for a TLS connection session in caOS.

Membri:

Nome	Tipo	Descrizione
io	ca_tls_io_t	Abstraction for underlying transport (e.g., TCP socket).
cfg	const ca_tls_config_t *	Pointer to TLS configuration (certificates, keys). Must remain valid for the session duration.
transcript	ca_sha256_ctx_t	Internal context for handshake integrity verification.
rd	ca_tls_dir_t	Read direction state (keys, IVs).
wr	ca_tls_dir_t	Write direction state (keys, IVs).
rd_encrypted	bool	True if incoming data is currently encrypted.
wr_encrypted	bool	True if outgoing data is currently encrypted.
established	bool	True if the TLS handshake is complete.
closed	bool	True if the connection is terminated.
alert	u8	Stores the last TLS alert code received or sent.
app_off	u32	Offset of unread application data in the RX buffer.
app_len	u32	Length of unread application data in the RX buffer.
rx	u8[]	Buffer for incoming encrypted/decrypted data.
tx	u8[]	Buffer for outgoing encrypted/decrypted data.
hs	u8[]	Buffer for handshake messages.
hs_len	u32	Current length of data in the handshake buffer.

Note:
The ca_tls_t structure is typically allocated by the application. It must be zero-initialized before use. The structure maintains its own internal buffers (rx, tx, hs) defined by macros. Ownership remains with the caller, but it is passed by pointer to ca_tls_* functions which modify its internal state.

Uso:
Used to manage a TLS session. Initialize the struct, then pass it to ca_tls_accept (for servers) or use it with ca_tls_read and ca_tls_write to perform secure communication over a transport layer.

Esempio:

```
ca_tls_t my_tls_session;
ca_memset(&my_tls_session, 0, sizeof(ca_tls_t));

/* Configure the session with a pre-defined config */
my_tls_session.cfg = &my_app_tls_config;

/* Perform TLS handshake as a server */
if (ca_tls_accept(&my_tls_session) == 0) {
    /* Connection established, ready to read/write */
    u8 buffer[64];
    ca_tls_read(&my_tls_session, buffer, sizeof(buffer));
}

/* Close the session when finished */
ca_tls_close(&my_tls_session);
```

---

ca_uart_baud_rate_t

Tipo: Enumerazione
File: caos/drivers/inc/uart.h:28:43

```
typedef enum {
CA_UART_BAUD_9600    = 9600,      /*!< 9600 bps */
CA_UART_BAUD_19200   = 19200,     /*!< 19200 bps */
CA_UART_BAUD_38400   = 38400,     /*!< 38400 bps */
CA_UART_BAUD_57600   = 57600,     /*!< 57600 bps */
CA_UART_BAUD_115200  = 115200,    /*!< 115200 bps */
CA_UART_BAUD_230400  = 230400,    /*!< 230400 bps */
CA_UART_BAUD_460800  = 460800,    /*!< 460800 bps */
CA_UART_BAUD_921600  = 921600,    /*!< 921600 bps */
CA_UART_BAUD_1000000 = 1000000,   /*!< 1 Mbps */
CA_UART_BAUD_2000000 = 2000000,   /*!< 2 Mbps */
CA_UART_BAUD_3000000 = 3000000,   /*!< 3 Mbps */
CA_UART_BAUD_4000000 = 4000000,   /*!< 4 Mbps - Theoretical maximum for
    some STM32 */
CA_UART_BAUD_4500000 = 4500000,   /*!< 4.5 Mbps - Practical maximum for
    some STM32 */
CA_UART_BAUD_5000000 = 5000000,   /*!< 5 Mbps - Theoretical maximum for
    some high-performance STM32 */
} ca_uart_baud_rate_t;
```

An enumeration defining the supported communication speeds (baud rates) for UART peripheral configuration.

Membri:

Nome	Tipo	Descrizione
`CA_UART_BAUD_9600 to CA_UART_BAUD_5000000`	`enum constant`	Represents the target baud rate in bits p (bps). Selecting a value unsupported by ware clock configuration may result in co tion errors.

Note:
This enum is used to map human-readable baud rates to the integer values required by the hardware abstraction layer. Ensure the selected baud rate is compatible with the STM32 peripheral clock frequency (PCLK) to avoid high bit-error rates.

Uso:
Used as a parameter in UART initialization structures or configuration functions to set the transmission speed of the serial interface.

Esempio:

```
ca_uart_config_t uart_cfg = { .baud_rate = CA_UART_BAUD_115200, .parity =
    CA_UART_PARITY_NONE, .stop_bits = CA_UART_STOP_1 };
```

`ca_uart_rx_cb_t`

Tipo: Callback
File: `caos/drivers/inc/uart.h:46:46`

```
typedef void (*ca_uart_rx_cb_t)(u32 rx_data)
```

A function pointer type used to define a callback function that executes when a byte is received via UART.

Membri:

Nome	Tipo	Descrizione
`rx_data`	`u32`	The 32-bit value containing the received byte. Only the lowest 8 bits are typically valid data; higher bits should be ignored unless specified by the driver.

Note:
This callback is executed within the UART interrupt service routine (ISR) context. It must be kept extremely short and efficient to avoid blocking other system interrupts. Do not perform heavy processing or blocking operations inside this function.

Uso:
Used when configuring a UART peripheral to handle incoming data asynchronously. You assign a function matching this signature to the UART configuration structure before initializing the driver.

Esempio:

```
void my_uart_handler(u32 rx_data) {
    uint8_t byte = (uint8_t)(rx_data & 0xFF);
    // Process the received byte
}

// Usage in configuration
ca_uart_cfg_t config = {
    .rx_cb = my_uart_handler,
    // ... other config fields
};
```

---

ca_udp_binding_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:69:72

```
typedef struct {
u16          port;           /* UDP port number (0 = unused slot) */
ca_udp_rx_t handler;         /* callback, NULL = port open but no handler
    */
} ca_udp_binding_t;
```

A structure defining a UDP port binding, mapping a specific port number to a callback function for incoming packet processing.

Membri:

Nome	Tipo	Descrizione
port	u16	The UDP port number to listen on. Set to 0 to indicate an unused or disabled slot in the binding table.
handler	ca_udp_rx_t	A function pointer to the callback executed when a packet arrives on this port. If NULL, the port is considered open but packets will be dropped.

Note:
This structure is typically used as an element within a static array defined in the network configuration. The system iterates through this array to register listeners. Ensure the array is large enough to accommodate all required services; otherwise, new bindings will fail to register.

Uso:
Use this type when configuring the network stack's UDP listener table. It is essential for routing incoming UDP traffic to specific application-level logic.

Esempio:

```
static void my_udp_handler(u16 port, const u8 *data, u16 len) { /* Process
    packet */ } static const ca_udp_binding_t my_bindings[] = { { .port = 5000,
    .handler = my_udp_handler }, { .port = 0, .handler = NULL } };
```

---

ca_udp_cfg_t

Tipo: Struttura
File: caos/net/inc/net_cfg.h:74:77

```
typedef struct {
ca_udp_binding_t bindings[CA_UDP_MAX_PORTS];
u16              count;      /* number of active bindings */
} ca_udp_cfg_t;
```

Configuration structure used to define and register multiple UDP port bindings for the network stack.

Membri:

Nome	Tipo	Descrizione
bindings	ca_udp_binding_t[]	An array of UDP binding structures defining local ports and their associated callback functions. Must not exceed CA_UDP_MAX_PORTS.
count	u16	The number of valid entries currently populated in the bindings array. Must be less than or equal to CA_UDP_MAX_PORTS.

Note:
This structure is typically passed to the network initialization routine. The user is responsible for allocating this structure, usually as a static global variable to ensure it persists throughout the application lifecycle. Do not modify the contents after the network stack has been initialized.

Uso:
Use this struct when configuring the UDP layer of the caOS network stack. It allows you to batch-register multiple UDP listeners (ports) during system startup.

Esempio:

```
ca_udp_cfg_t udp_config = {
    .bindings = {
        { .port = 8080, .callback = my_udp_handler },
        { .port = 9090, .callback = my_other_handler }
    },
    .count = 2
};

/* Pass this configuration to the network stack initialization */
ca_net_init(&udp_config);
```

---

ca_udp_cli_rx_t

Tipo: Callback
File: caos/net/inc/udp_client.h:53:53

```
typedef void (*ca_udp_cli_rx_t)(u8 handle,
```

A callback function type triggered by the caOS UDP client stack whenever a new packet is received.

Membri:

Nome	Tipo	Descrizione
`handle`	`u8`	The unique identifier of the UDP client instance that received the data. Must be a valid handle returned by the initialization function.
`data`	`u8*`	Pointer to the buffer containing the received payload. Valid only for the duration of the callback execution.
`len`	`u16`	The length of the received data in bytes. Must be checked against buffer limits to prevent overflows.

Note:
This callback is executed within the context of the network task. It must be kept short and non-blocking to avoid starving the network stack. The memory pointed to by 'data' is managed by the stack and should not be freed or modified by the user.

Uso:
Used during the registration of a UDP client. You assign a function of this type to the client configuration structure so the system knows where to route incoming UDP traffic.

Esempio:

```
void my_udp_rx_handler(u8 handle, u8 *data, u16 len) { if (len > 0) {
    process_packet(data, len); } } ... ca_udp_cli_cfg_t cfg = { .rx_cb =
    my_udp_rx_handler };
```

`ca_udp_client_cfg_t`

Tipo: Struttura
File: `caos/net/inc/udp_client.h:61:69`

```
typedef struct {
ca_ipv4_t          server_ip;
u16              server_port;
u16              local_port;          /* 0 = ephemeral (49152 + slot) */
u32              arp_timeout_ms;
ca_mac_t           local_mac;           /* our MAC (for TX frames) */
ca_ipv4_t          local_ip;            /* our IP  (for TX frames) */
ca_udp_cli_rx_t on_rx;              /* NULL = use blocking recv */
} ca_udp_client_cfg_t;
```

Configuration structure used to define the network parameters and callback behavior for a caOS UDP client instance.

Membri:

Nome	Tipo	Descrizione
server_ip	ca_ipv4_t	The destination IPv4 address of the remote server. Must be a valid unicast or broadcast address.
server_port	u16	The destination UDP port number on the remote server.
local_port	u16	The local UDP port to bind. Set to 0 to allow the system to assign an ephemeral port automatically.
arp_timeout_ms	u32	Timeout in milliseconds to wait for an ARP resolution before failing the transmission.
local_mac	ca_mac_t	The hardware MAC address assigned to the local network interface.
local_ip	ca_ipv4_t	The local IPv4 address assigned to the network interface.
on_rx	ca_udp_cli_rx_t	Callback function pointer triggered upon receiving data. If set to NULL, the client operates in blocking mode.

Note:
This structure is typically passed by value or reference to the client initialization function. The user is responsible for allocating this struct, usually on the stack or as a static global. Ensure all fields are initialized to zero before setting specific values to avoid undefined behavior from uninitialized memory.

Uso:
Use this struct when initializing a new UDP client instance to define its network identity and communication target. It is passed as an argument to the client creation API to configure the socket before it starts processing packets.

Esempio:

```
ca_udp_client_cfg_t cfg = {0};
cfg.server_ip = CA_IPV4(192, 168, 1, 100);
cfg.server_port = 5000;
cfg.local_port = 0;
cfg.arp_timeout_ms = 1000;
cfg.local_mac = my_mac_addr;
cfg.local_ip = my_ip_addr;
cfg.on_rx = my_rx_callback;

ca_udp_client_init(&client_handle, &cfg);
```

---

ca_udp_frame_t

Tipo: Struttura
File: caos/net/inc/net_proto.h:118:123

```
typedef struct {
u16    src_port;    /* source port big-endian */
u16    dst_port;    /* destination port big-endian */
u16    length;      /* header + data big-endian */
u16    checksum;    /* 0 = not present (RFC 768) big-endian */
} __attribute__((packed)) ca_udp_frame_t;
```

Represents the standard UDP header structure used for network packet construction and parsing.

Membri:

Nome	Tipo	Descrizione
src_port	u16	The source port number in big-endian format. Must be set to the sender's port.
dst_port	u16	The destination port number in big-endian format. Must be set to the receiver's port.
length	u16	Total length of the UDP header plus the payload in bytes, in big-endian format.
checksum	u16	UDP checksum in big-endian format. Set to 0 to indicate that no checksum is provided, as per RFC 768.

Note:
This struct is marked with ___attribute___((packed)) to ensure no padding bytes are inserted by the compiler, matching the exact binary layout of a network UDP header. All multi-byte fields must be converted to network byte order (big-endian) using functions like htons() before transmission.

Uso:
Used when manually crafting raw UDP packets or parsing incoming network buffers. It is typically cast onto a byte array pointer at the start of the UDP payload section of an IP packet.

Esempio:

```
ca_udp_frame_t *udp_hdr = (ca_udp_frame_t *)buffer_ptr;
udp_hdr->src_port = htons(8080);
udp_hdr->dst_port = htons(9090);
udp_hdr->length = htons(sizeof(ca_udp_frame_t) + data_len);
udp_hdr->checksum = 0;
```

---

ca_udp_rx_t

Tipo: Callback
File: caos/net/inc/net_cfg.h:65:65

```
typedef void (*ca_udp_rx_t)(u16 buf_idx)
```

A callback function type triggered by the network stack when a new UDP packet is received.

Membri:

Nome	Tipo	Descrizione
buf_idx	u16	The index of the internal network buffer containing the received packet data. Must be used with network retrieval functions to access the payload.

Note:
This callback is executed within the context of the network task or an ISR depending on the driver implementation. It must be kept short to avoid blocking network traffic. The buffer index is managed by the network stack; do not attempt to free or manually modify the buffer index directly.

Uso:
Used to register a custom handler in the network configuration structure. Assign a function pointer of this type to the UDP receive hook to process incoming data packets asynchronously.

Esempio:

```c
void my_udp_handler(u16 buf_idx) {
    uint8_t *data = net_get_buffer_ptr(buf_idx);
    uint16_t len = net_get_buffer_len(buf_idx);
    /* Process packet data here */
    net_release_buffer(buf_idx);
}

/* In initialization code */
ca_udp_rx_t my_callback = my_udp_handler;
```

---

ca_udp_server_cfg_t

Tipo: Struttura
File: caos/net/inc/udp_server.h:68:77

```c
typedef struct {
u16                 port;               /* UDP port to listen on */
u8                  max_clients;        /* <= UDPSRV_MAX_CLIENTS */
u32                 client_timeout_ms;  /* inactivity timeout */
mac_t               local_mac;          /* our MAC (for TX frames) */
ipv4_t              local_ip;           /* our IP  (for TX frames) */
ca_udp_srv_rx_t     on_rx;              /* mandatory */
ca_udp_srv_event_t  on_connect;         /* NULL ok */
ca_udp_srv_event_t  on_disconnect;      /* NULL ok */
} ca_udp_server_cfg_t;
```

Configuration structure used to initialize and define the behavior of a UDP server instance in caOS.

Membri:

Nome	Tipo	Descrizione
port	u16	The UDP port number the server will bind to. Must be a valid non-reserved port.
max_clients	u8	Maximum number of concurrent clients allowed. Must be less than or equal to UDPSRV_MAX_CLIENTS.
client_timeout_ms	u32	Inactivity duration in milliseconds before a client is automatically disconnected.
local_mac	ca_mac_t	The local MAC address used for outgoing UDP frames.
local_ip	ca_ipv4_t	The local IPv4 address assigned to the server interface.
on_rx	ca_udp_srv_rx_t	Mandatory callback function triggered when data is received from a client.
on_connect	ca_udp_srv_event_t	Optional callback triggered when a new client connects. Can be set to NULL.
on_disconnect	ca_udp_srv_event_t	Optional callback triggered when a client disconnects. Can be set to NULL.

Note:
The structure is typically allocated on the stack before passing it to the server initialization function. The user is responsible for ensuring the memory remains valid during the initialization call. The 'on_rx' callback is mandatory; failing to provide it will result in undefined behavior or initialization failure.

Uso:

Use this struct to configure a UDP server before calling the server start or initialization functions. It acts as the primary configuration object for the network stack's UDP layer.

Esempio:

```
ca_udp_server_cfg_t cfg = {0};
cfg.port = 8080;
cfg.max_clients = 5;
cfg.client_timeout_ms = 30000;
cfg.local_mac = my_mac_addr;
cfg.local_ip = my_ip_addr;
cfg.on_rx = my_rx_callback;
cfg.on_connect = NULL;
cfg.on_disconnect = NULL;
ca_udp_server_init(&cfg);
```

---

ca_udp_srv_client_info_t

Tipo: Struttura
File: caos/net/inc/udp_server.h:136:141

```
typedef struct {
bool    connected;
ca_ipv4_t src_ip;
u16     src_port;
u8    ring_used;    /* packets queued in ring */
} ca_udp_srv_client_info_t;
```

Represents the current connection state and metadata of a remote client interacting with a caOS UDP server.

Membri:

Nome	Tipo	Descrizione
connected	bool	Indicates if the client is currently tracked by the server. Set to true when a packet is received from a new or existing client.
src_ip	ca_ipv4_t	The IPv4 address of the remote client. Must be a valid ca_ipv4_t structure.
src_port	u16	The UDP source port of the client. Valid range is 1 to 65535.
ring_used	u8	The number of packets currently buffered in the client's specific ring buffer. If this reaches the maximum capacity, new packets may be dropped.

Note:
This structure is typically managed internally by the caOS UDP server stack. It is usually passed as a pointer to callback functions or status retrieval APIs. Do not manually modify the 'ring_used' field as it is managed by the network interrupt service routine.

Uso:
Use this structure when implementing a UDP server callback to identify the sender of a packet or to monitor the traffic load of specific clients.

Esempio:

```
void my_udp_callback(ca_udp_srv_client_info_t *client_info) {
    if (client_info->connected) {
        printf("Packet from: %d.%d.%d.%d:%d\n",
```

```
                client_info->src_ip.addr[0], client_info->src_ip.addr[1],
                client_info->src_ip.addr[2], client_info->src_ip.addr[3],
                client_info->src_port);
        if (client_info->ring_used > 5) {
            /* Handle potential congestion */
        }
    }
}
```

---

ca_udp_srv_event_t

Tipo: Callback
File: caos/net/inc/udp_server.h:61:61

```
typedef void (*ca_udp_srv_event_t)(u8 client_id,
```

A callback function type triggered by the caOS UDP server when a new packet is received from a client.

Membri:

Nome	Tipo	Descrizione
client_id	u8	A unique identifier assigned to the remote client. Valid range is 0-255. If invalid, the server cannot track the client session.
data	u8*	Pointer to the buffer containing the received payload. Must not be modified outside the callback scope.
len	u16	The length of the received data in bytes. Ensure this does not exceed your local processing buffer size.

Note:
This callback is executed within the context of the UDP server task. Keep the implementation short to avoid blocking the network stack. Do not perform long-running operations or blocking calls inside this function.

Uso:
Used when initializing a UDP server instance via the ca_udp_srv_init function to handle incoming network traffic asynchronously.

Esempio:

```
void my_udp_handler(u8 client_id, u8 *data, u16 len) { if (len > 0) { /* Process
    incoming data */ } }

ca_udp_srv_cfg_t config = { .port = 8080, .on_event = my_udp_handler };
ca_udp_srv_init(&config);
```

---

ca_udp_srv_rx_t

Tipo: Callback
File: caos/net/inc/udp_server.h:56:56

```
typedef void (*ca_udp_srv_rx_t)(u8 client_id,
```

A callback function type triggered by the caOS UDP server whenever a new packet is received from a client.

Membri:

Nome	Tipo	Descrizione
`client_id`	`u8`	The unique identifier for the client session. Valid range is 0-255. If invalid, the server cannot route the response back to the correct socket.
`data`	`const u8 *`	Pointer to the buffer containing the received payload. Must not be modified or freed by the callback.
`len`	`u16`	The length of the received data in bytes. Ensure bounds checking before accessing the data pointer.

Note:
This callback is executed within the context of the UDP server task. It must be non-blocking and should not perform heavy computations or long delays to avoid starving the network stack. The memory pointed to by 'data' is managed by the caOS network stack and is only guaranteed to be valid for the duration of the callback execution.

Uso:
Used when initializing a UDP server instance. You assign a function pointer of this type to the 'rx_callback' field in the server configuration structure to handle incoming network traffic.

Esempio:

```
void my_udp_handler(u8 client_id, const u8 *data, u16 len) { if (len > 0) { /* Process incoming data */ } } ... ca_udp_srv_cfg_t cfg = { .rx_callback = my_udp_handler, /* other fields */ };
```

`ca_usb_cb_t`

Tipo: Struttura
File: `caos/drivers/inc/usb.h:56:63`

```
typedef struct {
ca_usb_reset_cb_t     on_reset;
ca_usb_mounted_cb_t   on_mounted;
ca_usb_unmounted_cb_t on_unmounted;
ca_usb_setup_cb_t     on_setup;
ca_usb_rx_cb_t        on_rx;
ca_usb_tx_done_cb_t   on_tx_done;
} ca_usb_cb_t;
```

A structure containing function pointers (callbacks) to handle USB events and data transfers in the caOS USB stack.

Membri:

Nome	Tipo	Descrizione
on_reset	ca_usb_reset_cb_t	Triggered when the USB bus reset signal is detected. Used to re-initialize endpoints.
on_mounted	ca_usb_mounted_cb_t	Triggered when the device is successfully enumerated by the host.
on_unmounted	ca_usb_unmounted_cb_t	Triggered when the device is disconnected or the host resets the port.
on_setup	ca_usb_setup_cb_t	Triggered when a SETUP packet is received on endpoint 0. Essential for handling standard USB requests.
on_rx	ca_usb_rx_cb_t	Triggered when data is received on a non-control endpoint.
on_tx_done	ca_usb_tx_done_cb_t	Triggered when a previously initiated data transmission has completed successfully.

Note:
This structure acts as an interface between the hardware driver and your application logic. You must provide a pointer to an instance of this struct when initializing the USB peripheral. Ensure all pointers are either valid functions or NULL if the event does not need handling. The struct must remain in memory (e.g., static or global) as long as the USB peripheral is active.

Uso:
Use this struct to define the behavior of your USB device. Pass it to the USB initialization function to register your custom logic for handling host communication.

Esempio:

```
static void my_usb_reset(void) { /* Handle reset */ } static const ca_usb_cb_t
    my_usb_callbacks = { .on_reset = my_usb_reset, .on_mounted = NULL, .
    on_unmounted = NULL, .on_setup = NULL, .on_rx = NULL, .on_tx_done = NULL };
```

---

ca_usb_cdc_cfg_t

Tipo: Struttura
File: caos/usb/inc/usb_cdc.h:59:64

```
typedef struct {
ca_usb_device_type_t header;        /* tag + ops (D19)     first field
    */
u16  mps;                            /* Data bulk MPS (64 FS, 512 HS); 0
    = 64 */
void (*on_rx)  (const u8 *buf, u16 len);          /* data from host */
void (*on_line)(const ca_usb_cdc_line_t *line, u8 control);  /* opt. */
} __attribute__((aligned(4))) ca_usb_cdc_cfg_t;
```

Configuration structure for initializing a USB CDC (Communication Device Class) interface in caOS.

Membri:

Nome	Tipo	Descrizione
header	ca_usb_device_type_t	Must be the first field. Contains the device tag and operation pointers required by the caOS USB stack to identify the driver type.
mps	u16	Maximum Packet Size for bulk endpoints. Use 64 for Full Speed (FS) or 512 for High Speed (HS). Setting this to 0 defaults to 64 bytes.
on_rx	void (*)(const u8 *buf, u16 len)	Callback function triggered when data is received from the USB host. 'buf' points to the received data, 'len' is the number of bytes.
on_line	void (*)(const ca_usb_cdc_line_t *line, u8 control)	Optional callback for line coding changes (baud rate, parity) or control signals (DTR/RTS). Can be set to NULL if not required.

Note:
The structure must be 4-byte aligned as per the attribute. The user is responsible for allocating this structure, typically as a static global variable, as it must persist for the lifetime of the USB connection. The 'header' field must be correctly initialized with the appropriate caOS USB device tag before passing the struct to the registration function.

Uso:
Used during the initialization phase of the USB stack to register a CDC device. It defines how the application handles incoming data and line state changes from the host.

Esempio:

```
static void my_rx_handler(const u8 *buf, u16 len) { /* Process data */ };

ca_usb_cdc_cfg_t my_cdc_cfg = {
    .header = CA_USB_CDC_TAG,
    .mps = 64,
    .on_rx = my_rx_handler,
    .on_line = NULL
};

/* Pass the address of this struct to the caOS USB registration API */
ca_usb_register((ca_usb_device_type_t *)&my_cdc_cfg);
```

---

ca_usb_cdc_line_t

Tipo: Struttura
File: caos/usb/inc/usb_cdc.h:54:59

```
typedef struct {
u32 baud;         /* dwDTERate */
u8  stop_bits;    /* 0=1, 1=1.5, 2=2 */
u8  parity;       /* 0=none,1=odd,2=even,3=mark,4=space */
u8  data_bits;    /* 5,6,7,8,16 */
} ca_usb_cdc_line_t;
```

Represents the communication parameters (line coding) for a USB CDC virtual COM port.

Membri:

Nome	Tipo	Descrizione
baud	u32	The communication speed in bits per second (e.g., 115200). Must be a standard value supported by the hardware.
stop_bits	u8	Number of stop bits: 0 for 1 bit, 1 for 1.5 bits, 2 for 2 bits.
parity	u8	Parity mode: 0=none, 1=odd, 2=even, 3=mark, 4=space.
data_bits	u8	Number of data bits per frame. Valid values are 5, 6, 7, 8, or 16.

Note:
This structure is typically populated by the USB stack when the host sends a SET_LINE_CODING request. The application should treat this as a read-only configuration snapshot unless implementing a custom USB class driver.

Uso:
Used to configure the UART peripheral or software buffer settings when the USB host changes the virtual serial port parameters.

Esempio:

```
ca_usb_cdc_line_t line_config = { .baud = 115200, .stop_bits = 0, .parity = 0, .data_bits = 8 };

void apply_usb_settings(ca_usb_cdc_line_t *config) {
    // Example logic to update hardware UART based on USB host request
    UART_SetBaudrate(config->baud);
    UART_SetFrameFormat(config->data_bits, config->parity, config->stop_bits);
}
```

---

ca_usb_class_ops_t

Tipo: Struttura
File: caos/usb/inc/usb_mgmt.h:57:85

```
typedef struct ca_usb_class_ops_s {
/* Appende interface(+IAD)+endpoint descriptors al buffer; ritorna byte appesi.
*iface_num_inout    incrementato dell'iface count usato. */
u16  (*build_iface_desc)(const ca_usb_device_type_t *cfg,
u8 *buf, u16 max, u8 *iface_num_inout);
/* Contributo PID composito (D14): PID_BASE_x + USB_x_EP_DATA, o 0. */
u16  (*pid_contribution)(const ca_usb_device_type_t *cfg);
/* Notifiche driver (NULL-safe, fan-out a tutti i servizi attivi). */
void (*on_reset)    (const ca_usb_device_type_t *cfg);
void (*on_mounted)  (const ca_usb_device_type_t *cfg, ca_usb_speed_t speed);
void (*on_unmounted)(const ca_usb_device_type_t *cfg);
/* Apre/chiude gli EP del servizio (SET_CONFIGURATION). */
void (*on_configure)(const ca_usb_device_type_t *cfg);
/* SET_INTERFACE: il mgmt la invoca su OGNI servizio attivo passando iface
e alt richiesti. Il servizio confronta iface col proprio range e, se di
sua competenza, apre/chiude i bulk EP (NCM alt0=idle, alt1=active).
Ritorna true se iface e' di sua competenza (ferma l'iterazione). */
```

```
18 bool (*on_set_interface)(const ca_usb_device_type_t *cfg, u8 iface, u8
       alt);
19 /* Class SETUP (bmRequestType.Type=1). Ritorna true se gestito, false
        STALL. */
20 bool (*on_setup)    (const ca_usb_device_type_t *cfg, const u8 setup[8])
       ;
21 /* Fan-out EP I/O: il servizio filtra ep_addr (pu  essere ep_owns);
       ritorna
22 true se l'EP    suo (ferma l'iterazione). */
23 bool (*on_rx)       (const ca_usb_device_type_t *cfg, u8 ep_addr, u16
       len);
24 bool (*on_tx_done)  (const ca_usb_device_type_t *cfg, u8 ep_addr);
25 /* String descriptor per index > 3 (iMACAddress NCM, iInterface, ...).
       Scrive
26 in buf un USB string descriptor completo (bLength, bDescriptorType=0x03,
27 UTF-16LE) e ritorna la lunghezza; 0 se l'index non e' suo. */
28 u16  (*get_string)  (const ca_usb_device_type_t *cfg, u8 idx, u8 *buf,
       u16 max);
29 } ca_usb_class_ops_t;
```

A structure containing function pointers that define the behavior and interface of a specific USB class driver in caOS.

Membri:

Nome	Tipo	Descrizione
build_iface_desc	u16 (*)(const ca_usb_device_type_t *, u8 *, u16, u8 *)	Callback to append USB descriptors to the provided buffer. Must increment iface_num_inout by the number of interfaces used.
pid_contribution	u16 (*)(const ca_usb_device_type_t *)	Returns the PID offset contribution for composite devices. Return 0 if not applicable.
on_reset	void (*)(const ca_usb_device_type_t *)	Called when a USB bus reset occurs. Used to reset internal state.
on_mounted	void (*)(const ca_usb_device_type_t *, ca_usb_speed_t)	Called when the device is successfully enumerated and mounted.
on_unmounted	void (*)(const ca_usb_device_type_t *)	Called when the device is disconnected or unmounted.
on_configure	void (*)(const ca_usb_device_type_t *)	Called during SET_CONFIGURATION to initialize endpoints.
on_set_interface	bool (*)(const ca_usb_device_type_t *, u8, u8)	Handles SET_INTERFACE requests. Return true if the interface index belongs to this class.
on_setup	bool (*)(const ca_usb_device_type_t *, const u8[8])	Handles class-specific SETUP requests. Return true if handled, false to trigger a STALL.
on_rx	bool (*)(const ca_usb_device_type_t *, u8, u16)	Called when data is received on an endpoint. Return true if the endpoint belongs to this class.
on_tx_done	bool (*)(const ca_usb_device_type_t *, u8)	Called when a transmission is complete on an endpoint.
get_string	u16 (*)(const ca_usb_device_type_t *, u8, u8 *, u16)	Provides string descriptors for indices > 3. Returns length of written descriptor or 0 if index is unknown.

Note:
This structure is typically defined as a constant global variable in your driver file. The caOS

USB management layer uses these pointers to perform 'fan-out' calls to all registered services. Ensure all pointers are set to NULL if not implemented to avoid crashes.

Uso:
Used when implementing a custom USB class (e.g., CDC, HID, or vendor-specific). You register this structure with the caOS USB stack during system initialization to link your driver logic to the USB hardware events.

Esempio:

```
static u16 my_class_build_iface(const ca_usb_device_type_t *cfg, u8 *buf, u16
    max, u8 *iface_num) { /* Implementation */ return 0; } static const
    ca_usb_class_ops_t my_usb_ops = { .build_iface_desc = my_class_build_iface,
    .on_reset = NULL, .on_mounted = NULL, .on_unmounted = NULL, .on_configure =
    NULL, .on_set_interface = NULL, .on_setup = NULL, .on_rx = NULL, .on_tx_done
     = NULL, .get_string = NULL };
```

---

ca_usb_custom_cfg_t

Tipo: Struttura
File: caos/usb/inc/usb_custom.h:36:44

```
typedef struct {
ca_usb_device_type_t header;        /* tag + ops (D19) */
u8   ep_data;                        /* data EP number (1..N), IN+OUT
    bulk */
u16  mps;                            /* bulk MPS (64 FS, 512 HS) */
void (*on_rx)     (u8 ep_addr, u16 len);
void (*on_tx_done)(u8 ep_addr);
void (*on_mounted)(void);            /* opt.: host has enumerated the
    device */
void (*on_unmounted)(void);          /* opt.: cable disconnected / host
    suspended */
} __attribute__((aligned(4))) ca_usb_custom_cfg_t;
```

Configuration structure used to define the behavior and callbacks for a custom USB device interface in caOS.

Membri:

Nome	Tipo	Descrizione
header	ca_usb_device_type_t	Contains the device tag and operation pointers. Must be initialized to identify the device class.
ep_data	u8	The endpoint number for bulk data transfer. Valid range is 1 to N, representing both IN and OUT directions.
mps	u16	Maximum Packet Size. Use 64 for Full Speed (FS) or 512 for High Speed (HS) operation.
on_rx	void (*)(u8, u16)	Callback triggered when data is received. Receives the endpoint address and length of data.
on_tx_done	void (*)(u8)	Callback triggered after a transmission is completed on the specified endpoint.
on_mounted	void (*)(void)	Optional callback executed when the USB host successfully enumerates the device.
on_unmounted	void (*)(void)	Optional callback executed when the USB cable is disconnected or the host suspends the device.

Note:

The structure must be 4-byte aligned as per the attribute. The user is responsible for allocating this structure, typically in static memory or global scope, as it must persist for the lifetime of the USB connection. Do not free this memory while the USB stack is active.

Uso:
Used during the initialization phase of a custom USB device to register the endpoint configuration and event handlers with the caOS USB stack.

Esempio:

```
static void my_rx_handler(u8 ep, u16 len) { /* Handle data */ } static void
    my_tx_handler(u8 ep) { /* Handle completion */ } ca_usb_custom_cfg_t
    my_usb_cfg = { .header = CA_USB_TYPE_CUSTOM, .ep_data = 1, .mps = 64, .on_rx
     = my_rx_handler, .on_tx_done = my_tx_handler, .on_mounted = NULL, .
    on_unmounted = NULL };
```

---

ca_usb_dbg_t

Tipo: Struttura
File: caos/drivers/inc/usb.h:131:167

```
typedef struct {
/* event counters (all families) */
u32 rst;
u32 enumdne;
u32 susp;
u32 wkup;
u32 setup;
u32 rxflvl;
u32 rx_push;
u32 rx_drop_full;
u32 oep_xfrc[USB_EP_MAX];
u32 iep_xfrc[USB_EP_MAX];
u32 ep_read [USB_EP_MAX];
u32 ep_write[USB_EP_MAX];
u32 wr_full [USB_EP_MAX];
/* EP state snapshot (H5xx USB_DRD_FS; zero on other families) */
u32 chep    [USB_EP_MAX];   /* Raw R_CHEP: STAT_RX[13:12], STAT_TX[5:4],
    DTOG, VTRX/VTTX */
u8  rxq_h   [USB_EP_MAX];   /* ring RX head (ISR) / tail (ep_read) */
u8  rxq_t   [USB_EP_MAX];
u8  txq_h   [USB_EP_MAX];   /* ring TX head (ep_write) / tail (ISR) */
u8  txq_t   [USB_EP_MAX];
u8  tx_act  [USB_EP_MAX];   /* an IN packet is armed in PMA */
u32 rx_drop [USB_EP_MAX];   /* OUT ACKed by HW but RX ring full -> lost
   */
u32 rx_cnt0 [USB_EP_MAX];   /* OUT received by ISR with cnt==0 */
u32 rx_len0 [USB_EP_MAX];   /* rxq entry with len==0 consumed by ep_read
    */
/* DWT cycle counter measurements (H7xx     zero on other families) */
u32 isr_rx_sum;
u32 isr_rx_max;
u32 isr_rx_cnt;
u32 iat_sum;
u32 iat_max;
u32 iat_min;
u32 iat_cnt;
```

```
u32 lat_sum[USB_EP_MAX];
u32 lat_max[USB_EP_MAX];
u32 lat_cnt[USB_EP_MAX];
} ca_usb_dbg_t;
```

A structure containing diagnostic counters and state snapshots for USB peripheral debugging.

Membri:

Nome	Tipo	Descrizione
rst	u32	Number of USB reset events detected.
enumdne	u32	Number of enumeration done events.
susp	u32	Number of suspend events.
wkup	u32	Number of wakeup events.
setup	u32	Number of SETUP packet events.
rxflvl	u32	Number of RX FIFO level interrupts.
rx_push	u32	Total packets pushed to RX ring buffer.
rx_drop_full	u32	Total packets dropped due to full RX ring buffer.
oep_xfrc	u32[]	Transfer complete events for OUT endpoints.
iep_xfrc	u32[]	Transfer complete events for IN endpoints.
ep_read	u32[]	Number of read operations per endpoint.
ep_write	u32[]	Number of write operations per endpoint.
wr_full	u32[]	Number of times write buffer was full per endpoint.
chep	u32[]	Raw hardware endpoint status register snapshot.
rxq_h	u8[]	RX ring buffer head index per endpoint.
rxq_t	u8[]	RX ring buffer tail index per endpoint.
txq_h	u8[]	TX ring buffer head index per endpoint.
txq_t	u8[]	TX ring buffer tail index per endpoint.
tx_act	u8[]	Flag indicating if an IN packet is currently armed in PMA.
rx_drop	u32[]	Packets dropped because RX ring was full.
rx_cnt0	u32[]	Count of zero-length packets received by ISR.
rx_len0	u32[]	Count of zero-length entries consumed by ep_read.
isr_rx_sum	u32	Sum of DWT cycles for RX ISR processing (H7xx only).
isr_rx_max	u32	Maximum DWT cycles for RX ISR processing (H7xx only).
isr_rx_cnt	u32	Count of RX ISR measurements (H7xx only).
iat_sum	u32	Sum of inter-arrival times (H7xx only).
iat_max	u32	Maximum inter-arrival time (H7xx only).
iat_min	u32	Minimum inter-arrival time (H7xx only).
iat_cnt	u32	Count of inter-arrival measurements (H7xx only).
lat_sum	u32[]	Sum of latency measurements per endpoint (H7xx only).
lat_max	u32[]	Maximum latency per endpoint (H7xx only).
lat_cnt	u32[]	Count of latency measurements per endpoint (H7xx only).

Note:
This structure is populated by the USB driver's internal diagnostic functions. It is typically allocated by the caller on the stack or as a static variable. The fields are updated by the USB ISR and driver functions. On non-H7xx/H5xx families, many fields (like DWT measurements or raw EP snapshots) will remain zero.

Uso:

Use this structure to retrieve and inspect the internal state of the USB peripheral for debugging communication issues, packet loss, or performance bottlenecks. Pass a pointer to this struct to the appropriate ca_usb_dbg_* functions.

Esempio:

```c
#include "caos/drivers/inc/usb.h"

void print_usb_stats(void) {
    ca_usb_dbg_t stats;

    /* Clear the structure before filling it */
    ca_memzero(&stats, sizeof(ca_usb_dbg_t));

    /* Retrieve current USB FS statistics */
    ca_usb_dbg_fs_stat(&stats);

    /* Print the number of reset events */
    ca_printf("USB Resets: %u\n", stats.rst);
}
```

---

ca_usb_dev_ops_t

Tipo: Struttura
File: `caos/drivers/inc/usb.h:66:81`

```c
typedef struct {
void            (*clock_init)    (u32 usb_num);
void            (*gpio_init)     (u32 usb_num);
bool            (*init)          (u32 usb_num, const ca_usb_cb_t *cb);
bool            (*ep_open)       (u32 usb_num, u8 ep_addr,
    ca_usb_ep_type_t type, u16 mps);
bool            (*ep_write)      (u32 usb_num, u8 ep_addr, const u8 *buf,
     u16 len);
u16             (*ep_read)       (u32 usb_num, u8 ep_addr, u8 *buf, u16
    max_len);
void            (*set_address)   (u32 usb_num, u8 addr);
ca_usb_speed_t  (*get_speed)     (u32 usb_num);
void            (*connect)       (u32 usb_num);
void            (*disconnect)    (u32 usb_num);
void            (*ep_stall)      (u32 usb_num, u8 ep_addr);
bool            (*ep_close)      (u32 usb_num, u8 ep_addr);
bool            (*ep_clear_stall)(u32 usb_num, u8 ep_addr);
bool            (*ep_is_stalled) (u32 usb_num, u8 ep_addr);
} ca_usb_dev_ops_t;
```

A structure containing function pointers that define the hardware-specific operations for a USB controller.

Membri:

Nome	Tipo	Descrizione
clock_init	void (*)(u32)	Configures the peripheral clock. Must be called before any other USB operation.
gpio_init	void (*)(u32)	Configures the physical pins (D+/D-) for USB communication.
init	bool (*)(u32, const ca_usb_cb_t *)	Initializes the USB controller and registers the callback structure. Returns true on success.
ep_open	bool (*)(u32, u8, ca_usb_ep_type_t, u16)	Configures a specific endpoint. ep_addr is the hardware address, type defines the transfer mode, mps is the max packet size.
ep_write	bool (*)(u32, u8, const u8 *, u16)	Queues data to be sent from the specified endpoint. Returns true if the transfer was initiated.
ep_read	u16 (*)(u32, u8, u8 *, u16)	Reads received data from the endpoint buffer into the provided memory. Returns the number of bytes read.
set_address	void (*)(u32, u8)	Sets the USB device address assigned by the host during enumeration.
get_speed	ca_usb_speed_t (*)(u32)	Returns the current negotiated connection speed (e.g., Full Speed, High Speed).
connect	void (*)(u32)	Enables the pull-up resistor on the D+ line to signal presence to the host.
disconnect	void (*)(u32)	Disables the pull-up resistor to simulate a physical unplug event.
ep_stall	void (*)(u32, u8)	Forces the endpoint into a STALL state, indicating a protocol error or lack of resources.
ep_close	bool (*)(u32, u8)	Disables the specified endpoint and releases associated hardware resources.
ep_clear_stall	bool (*)(u32, u8)	Clears the STALL condition on an endpoint to resume normal operation.
ep_is_stalled	bool (*)(u32, u8)	Checks if the specified endpoint is currently in a STALL state.

Note:
This struct acts as a Hardware Abstraction Layer (HAL). It is typically defined as a 'const' global variable in a driver file (e.g., usb_stm32.c) and passed to the caOS USB stack during initialization. The user does not allocate this; it is provided by the board support package.

Uso:
Use this to implement or interface with low-level USB hardware drivers. It allows the caOS USB stack to remain hardware-agnostic by calling these function pointers instead of direct register manipulation.

Esempio:

```
static const ca_usb_dev_ops_t my_usb_ops = {
    .clock_init = stm32_usb_clock_init,
    .gpio_init = stm32_usb_gpio_init,
    .init = stm32_usb_init,
    .ep_open = stm32_usb_ep_open,
    .ep_write = stm32_usb_ep_write,
    .ep_read = stm32_usb_ep_read,
    .set_address = stm32_usb_set_address,
    .get_speed = stm32_usb_get_speed,
    .connect = stm32_usb_connect,
    .disconnect = stm32_usb_disconnect,
    .ep_stall = stm32_usb_ep_stall,
    .ep_close = stm32_usb_ep_close,
    .ep_clear_stall = stm32_usb_ep_clear_stall,
    .ep_is_stalled = stm32_usb_ep_is_stalled
};
```

---

ca_usb_dfu_cfg_t

Tipo: Struttura
File: caos/usb/inc/usb_dfu.h:54:63

```
typedef struct {
ca_usb_device_type_t header;        /* tag + ops (D19) */
u16  detach_timeout_ms;             /* wDetachTimeOut in the functional
    desc */
u16  transfer_size;                 /* wTransferSize in the functional
    desc */
u8   attributes;                    /* bmAttributes (USB_DFU_ATTR_*); 0
       WILL_DETACH */
const char *iface_str;              /* iInterface (e.g. "caOS DFU");
    NULL     none */
/* Host requested DFU_DETACH: the app must switch to DFU mode (e.g. flag
no-init + reset to bootloader). NULL     DETACH ignored (ACK only). */
void (*on_detach)(void);
} __attribute__((aligned(4))) ca_usb_dfu_cfg_t;
```

Configuration structure for the USB Device Firmware Upgrade (DFU) interface in caOS.

Membri:

Nome	Tipo	Descrizione
header	ca_usb_device_type_t	Standard USB device header containing the interface tag and operation pointers. Must be initialized correctly to link the DFU interface to the USB stack.
detach_timeout_ms	u16	Time in milliseconds the host waits for the device to detach and re-enumerate in DFU mode. Typical values range from 100 to 1000.
transfer_size	u16	The size of the data blocks transferred during firmware upload/download. Must match the hardware buffer constraints, typically 64, 128, or 256 bytes.
attributes	u8	Bitmask defining DFU capabilities (e.g., can download, can upload). Set to 0 for default behavior (WILL_DETACH).
iface_str	const char *	Optional string descriptor for the DFU interface shown in the device manager. Set to NULL if no string is required.
on_detach	void (*)(void)	Callback function triggered when the host sends a DFU_DETACH request. The application should use this to set a bootloader flag and perform a system reset.

Note:
The structure must be aligned to 4 bytes as per the attribute. It is typically allocated in static memory or global scope as it must persist for the lifetime of the USB interface. The user is responsible for providing a valid callback if they wish to support automatic transition to the bootloader.

Uso:
Used when initializing the USB stack to register the DFU class. Pass this structure to the USB interface registration function to enable firmware updates over USB.

Esempio:

```
static void my_detach_handler(void) { /* Set bootloader flag and reset */
    NVIC_SystemReset(); } static const ca_usb_dfu_cfg_t my_dfu_cfg = { .header =
     { .tag = CA_USB_TAG_DFU }, .detach_timeout_ms = 250, .transfer_size = 128,
    .attributes = 0, .iface_str = "caOS DFU", .on_detach = my_detach_handler };
```

---

ca_usb_ep_type_t

Tipo: Enumerazione
File: caos/drivers/inc/usb.h:35:40

```
typedef enum {
USB_EP_TYPE_CTRL = 0,
USB_EP_TYPE_ISOC = 1,
USB_EP_TYPE_BULK = 2,
USB_EP_TYPE_INTR = 3,
} ca_usb_ep_type_t;
```

Defines the transfer type for a USB endpoint, determining how data is scheduled and handled by the USB controller.

Membri:

Nome	Tipo	Descrizione
`CA_USB_EP_TYPE_CTRL`	`enum value`	Control transfer type. Used for device enumeration and configuration. Mandatory for Endpoint 0.
`CA_USB_EP_TYPE_ISOC`	`enum value`	Isochronous transfer type. Used for time-sensitive data like audio/video where delivery speed is prioritized over error correction.
`CA_USB_EP_TYPE_BULK`	`enum value`	Bulk transfer type. Used for large data transfers where reliability is critical, such as file transfers or mass storage.
`CA_USB_EP_TYPE_INTR`	`enum value`	Interrupt transfer type. Used for small, low-latency data packets, such as mouse movements or keyboard presses.

Note:
This enum is used to configure the hardware registers of the STM32 USB peripheral. It must be set correctly during the endpoint initialization phase. Incorrect assignment will result in the USB host rejecting the device descriptor or failing to communicate with the specific endpoint.

Uso:
Used when defining the endpoint configuration structure before calling the USB driver initialization functions to register endpoints with the USB stack.

Esempio:

```
ca_usb_ep_type_t my_ep_type = CA_USB_EP_TYPE_BULK;

// Example of assigning the type to an endpoint configuration struct
struct usb_ep_config {
    uint8_t ep_addr;
    ca_usb_ep_type_t type;
    uint16_t max_packet_size;
};

struct usb_ep_config bulk_in = {
    .ep_addr = 0x81,
    .type = my_ep_type,
    .max_packet_size = 64
};
```

`ca_usb_mounted_cb_t`

Tipo: Callback
File: `caos/drivers/inc/usb.h:50:50`

```
typedef void (*ca_usb_mounted_cb_t)(ca_usb_speed_t speed)
```

A callback function type triggered by the USB driver when the device successfully completes enumeration and is mounted by the host.

Membri:

Nome	Tipo	Descrizione
`speed`	`ca_usb_speed_t`	Indicates the negotiated USB speed (e.g., Full Speed or High Speed). Incorrect handling of speed-specific buffers or endpoints may lead to communication errors.

Note:

This callback is executed within the context of the USB interrupt or the USB task, depending on the driver implementation. It must be kept short and non-blocking to avoid stalling the USB stack. The user is responsible for registering this callback via the driver configuration structure before initializing the USB peripheral.

Uso:
Use this callback to perform application-level initialization that requires the USB bus to be active, such as enabling specific USB classes (CDC, HID) or notifying the main application state machine that the device is ready for data transfer.

Esempio:

```
void my_usb_mounted_handler(ca_usb_speed_t speed) {
    if (speed == CA_USB_SPEED_FULL) {
        log_info("USB mounted at Full Speed");
    }
    app_state = APP_READY;
}

ca_usb_config_t usb_cfg = {
    .on_mounted = my_usb_mounted_handler
};
ca_usb_init(&usb_cfg);
```

---

ca_usb_msc_cfg_t

Tipo: Struttura
File: caos/usb/inc/usb_msc.h:56:63

```
typedef struct {
ca_usb_device_type_t header;        /* tag + ops (D19)     first field */
u16  mps;                            /* Bulk MPS (64 FS, 512 HS); 0 = 64 */
u32  block_size;                     /* typically 512 */
u32  block_count;                    /* total number of blocks (capacity) */
bool (*read) (u32 lba, u8 *buf, u32 count);
bool (*write)(u32 lba, const u8 *buf, u32 count);
} __attribute__((aligned(4))) ca_usb_msc_cfg_t;
```

Configuration structure for defining a USB Mass Storage Class (MSC) device interface in caOS.

Membri:

Nome	Tipo	Descrizione
header	ca_usb_device_type_t	Must be the first member; contains the device tag and operation pointers required by the caOS USB stack.
mps	u16	Maximum Packet Size for Bulk endpoints. Use 64 for Full Speed (FS) or 512 for High Speed (HS). Set to 0 to default to 64.
block_size	u32	Size of a single logical block in bytes, typically 512 for standard storage media.
block_count	u32	Total number of addressable blocks available on the storage medium.
read	bool (*)(u32, u8 *, u32)	Callback function pointer for reading data from the storage medium. Returns true on success, false on failure.
write	bool (*)(u32, const u8 *, u32)	Callback function pointer for writing data to the storage medium. Returns true on success, false on failure.

Note:
The structure must be 4-byte aligned as per the attribute. The user is responsible for allocating this structure, typically in static memory or global scope, as it must persist for the lifetime of the USB MSC service. The callbacks must be thread-safe if the underlying storage driver is accessed by other tasks.

Uso:
Used to register a custom storage backend (like an SD card or Flash memory) with the caOS USB MSC driver. Pass a pointer to this struct when initializing the USB MSC peripheral.

Esempio:

```
static bool my_read(u32 lba, u8 *buf, u32 count) { /* Read logic */ return true; }
static bool my_write(u32 lba, const u8 *buf, u32 count) { /* Write logic */ return true; }

ca_usb_msc_cfg_t my_msc_cfg = {
    .header = { .tag = CA_USB_MSC_TAG },
    .mps = 512,
    .block_size = 512,
    .block_count = 1024,
    .read = my_read,
    .write = my_write
};
```

---

ca_usb_ncm_cfg_t

Tipo: Struttura
File: caos/usb/inc/usb_ncm.h:71:76

```
typedef struct {
ca_usb_device_type_t header;     /* tag + ops (D19)      first field */
u16  mps;                         /* Bulk MPS (64 FS); 0 = 64 */
u8   mac[6];                      /* MAC exposed to the host (iMACAddress) */
ca_usb_ncm_rx_cb_t on_rx;         /* received Ethernet datagram */
} __attribute__((aligned(4))) ca_usb_ncm_cfg_t;
```

Configuration structure for initializing a USB Network Control Model (NCM) device interface.

Membri:

Nome	Tipo	Descrizione
`header`	`ca_usb_device_t`	Standard USB device header containing the device tag and operation table. Must be initialized with the appropriate NCM device type constant.
`mps`	`u16`	Maximum Packet Size for Bulk endpoints. Set to 0 to default to 64 bytes (Full Speed). Incorrect values may cause USB enumeration failures.
`mac`	`u8[6]`	The 6-byte hardware MAC address reported to the host via the iMACAddress descriptor. Must be unique on the network.
`on_rx`	`ca_usb_ncm_rx_cb_t`	Callback function pointer triggered when an Ethernet datagram is received from the host. Must not be NULL.

Note:
The structure must be 4-byte aligned as per the attribute. The user is responsible for allocating this struct, typically in static memory or global scope, as it must persist for the lifetime of the USB interface. Do not modify fields after the USB stack has been initialized.

Uso:
Used as the configuration parameter when registering or initializing an NCM USB class instance in the caOS USB stack.

Esempio:

```
static void my_rx_handler(const void *data, size_t len) { /* Process packet */ }
    static const ca_usb_ncm_cfg_t ncm_cfg = { .header = { .tag = CA_USB_DEV_NCM
    }, .mps = 512, .mac = {0x02, 0x00, 0x00, 0x00, 0x00, 0x01}, .on_rx =
   my_rx_handler };
```

`ca_usb_ncm_rx_cb_t`

Tipo: Callback
File: `caos/usb/inc/usb_ncm.h:71:71`

```
typedef void (*ca_usb_ncm_rx_cb_t)(const u8 *eth, u16 len)
```

A callback function type triggered by the caOS USB NCM stack whenever a new Ethernet frame is received.

Membri:

Nome	Tipo	Descrizione
`eth`	`const u8 *`	Pointer to the start of the received Ethernet frame buffer. Must be treated as read-only.
`len`	`u16`	The length of the received Ethernet frame in bytes.

Note:
This callback is executed within the context of the USB interrupt or the USB task. It must be kept as short as possible to avoid blocking the USB stack. The memory pointed to by 'eth' is owned by the USB driver and is only valid for the duration of the callback; do not store this pointer for later use.

Uso:

Used to register a custom handler for incoming network traffic. You assign a function of this type to the NCM configuration structure before initializing the USB NCM interface.

Esempio:

```
void my_ncm_rx_handler(const u8 *eth, u16 len) {
    if (len > 0) {
        process_packet(eth, len);
    }
}

// During initialization
ca_usb_ncm_config_t config;
config.rx_cb = my_ncm_rx_handler;
ca_usb_ncm_init(&config);
```

`ca_usb_reset_cb_t`

Tipo: Callback
File: `caos/drivers/inc/usb.h:49:49`

```
typedef void (*ca_usb_reset_cb_t)(void)
```

A function pointer type used to define a callback that executes when the USB bus receives a reset signal.

Membri:

Nome	Tipo	Descrizione
`void`	`void`	The callback takes no arguments and returns no value.

Note:
This callback is triggered by the USB hardware interrupt service routine. It must be kept extremely short and non-blocking to avoid delaying USB stack processing. It is typically registered during the USB driver initialization phase.

Uso:
Use this type when you need to perform specific hardware or software resets (e.g., clearing buffers or resetting state machines) immediately after the USB host initiates a bus reset.

Esempio:

```
void my_usb_reset_handler(void) {
    // Reset application-specific USB state
    my_app_buffer_index = 0;
}

// Registering the callback
ca_usb_set_reset_callback(my_usb_reset_handler);
```

`ca_usb_rx_cb_t`

Tipo: Callback
File: `caos/drivers/inc/usb.h:53:53`

```
typedef void (*ca_usb_rx_cb_t)(u8 ep_addr, u16 len)
```

A function pointer type used to define a callback that executes when the USB peripheral receives data on a specific endpoint.

Membri:

Nome	Tipo	Descrizione
`ep_addr`	`u8`	The address of the USB endpoint that received the data. Must match the endpoint configured during initialization.
`len`	`u16`	The number of bytes received in the current packet. Value ranges from 0 up to the maximum packet size defined for the endpoint.

Note:
This callback is triggered within the USB interrupt context. Keep the implementation short and non-blocking. Do not perform heavy processing or blocking RTOS calls here; instead, signal a task or use a queue to process the data.

Uso:
Used when registering a USB driver configuration. You assign a function matching this signature to the driver's receive callback field so the system knows which code to run when data arrives.

Esempio:

```
void my_usb_rx_handler(u8 ep_addr, u16 len) { if (ep_addr == 0x01) { /* Signal a task to read data */ } } ca_usb_config_t config = { .rx_cb = my_usb_rx_handler };
```

`ca_usb_setup_cb_t`

Tipo: Callback
File: `caos/drivers/inc/usb.h:52:52`

```
typedef void (*ca_usb_setup_cb_t)(const u8 setup[8])
```

A callback function type triggered by the USB driver when a SETUP packet is received from the host.

Membri:

Nome	Tipo	Descrizione
`setup`	`const u8[8]`	An 8-byte array containing the raw USB SETUP request data (bmRequestType, bRequest, wValue, wIndex, wLength). Must be treated as read-only.

Note:
This callback is executed within the USB interrupt context or a high-priority system task. Keep the implementation extremely short; do not perform blocking operations or heavy processing here. The memory for the setup array is managed by the USB hardware peripheral and is only valid for the duration of the callback execution.

Uso:
Used to handle custom USB control requests (e.g., vendor-specific commands or class-specific requests). You register this callback during the USB device initialization phase to allow your application to parse and respond to incoming control transfers.

Esempio:

```c
void my_usb_setup_handler(const u8 setup[8]) {
    if (setup[0] == 0xC0 && setup[1] == 0x01) {
        // Handle custom vendor request 0x01
    }
}

// During initialization:
ca_usb_set_setup_callback(my_usb_setup_handler);
```

---

ca_usb_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/usb.h:42:45

```c
typedef enum {
USB_SPEED_FS = 0,    /* Full Speed 12 Mbit/s  */
USB_SPEED_HS = 1,    /* High Speed 480 Mbit/s */
} ca_usb_speed_t;
```

An enumeration defining the operational data rate for the USB peripheral.

Membri:

Nome	Tipo	Descrizione
CA_USB_SPEED_FS	enum constant	Full Speed mode, operating at 12 Mbit/s. Use this for standard USB 1.1/2.0 compatibility.
CA_USB_SPEED_HS	enum constant	High Speed mode, operating at 480 Mbit/s. Requires hardware support and appropriate PHY configuration.

Note:
This enum is used to configure the USB controller's clock and physical layer settings. Ensure the selected speed matches the capabilities of your hardware design and the connected device requirements.

Uso:
Used during the initialization phase of the USB driver to specify the desired bus speed before the USB stack is started.

Esempio:

```c
ca_usb_speed_t my_speed = CA_USB_SPEED_FS;

/* Configure the USB peripheral with the selected speed */
if (usb_init(my_speed) != CA_OK) {
    /* Handle initialization error */
}
```

---

ca_usb_tx_done_cb_t

Tipo: Callback
File: caos/drivers/inc/usb.h:54:54

```c
typedef void (*ca_usb_tx_done_cb_t)(u8 ep_addr)
```

A callback function type triggered by the USB driver when a data transmission (TX) operation is successfully completed.

Membri:

Nome	Tipo	Descrizione
`ep_addr`	`u8`	The address of the USB endpoint that finished sending data. Valid values are standard USB endpoint addresses (e.g., 0x81 for IN endpoint 1). Incorrect handling may lead to logic errors if the application tracks multiple endpoints.

Note:
This callback is executed within the context of the USB interrupt service routine (ISR). It must be kept extremely short and non-blocking. Do not perform heavy processing or call blocking RTOS primitives inside this function. The user is responsible for providing the function pointer, while the caOS USB driver manages the invocation.

Uso:
Used when registering a USB device configuration or initiating a transmission. It allows the application to know exactly when the hardware buffer is free to accept new data, preventing data loss or buffer overwrites.

Esempio:

```
void my_tx_complete_handler(u8 ep_addr) {
    if (ep_addr == 0x81) {
        // Signal a task that the buffer is ready for more data
        os_sem_post(&tx_ready_sem);
    }
}

// Usage in driver configuration
ca_usb_config_t config = {
    .tx_done_cb = my_tx_complete_handler
};
```

`ca_usb_type_t`

Tipo: Enumerazione
File: `caos/usb/inc/usb_mgmt.h:41:49`

```
typedef enum {
CA_USB_TYPE_NONE  = 0,
CA_USB_TYPE_CDC   = 1,
CA_USB_TYPE_MSC   = 2,
CA_USB_TYPE_NCM   = 3,
CA_USB_TYPE_DFU   = 4,
CA_USB_TYPE_CUSTOM = 5,   /* servizio vendor custom (step 6) */
CA_USB_TYPE__MAX
} ca_usb_type_t;
```

An enumeration defining the specific USB class or protocol mode supported by the caOS USB stack.

Membri:

Nome	Tipo	Descrizione
CA_USB_TYPE_NONE	enum value	USB interface is disabled or not initialized. Default state.
CA_USB_TYPE_CDC	enum value	Communication Device Class, typically used for virtual COM ports.
CA_USB_TYPE_MSC	enum value	Mass Storage Class, used for file system access (e.g., USB flash drive emulation).
CA_USB_TYPE_NCM	enum value	Network Control Model, used for Ethernet-over-USB networking.
CA_USB_TYPE_DFU	enum value	Device Firmware Upgrade, used for bootloader and firmware update procedures.
CA_USB_TYPE_CUSTOM	enum value	Vendor-specific protocol implementation.
CA_USB_TYPE__MAX	enum value	Boundary marker for validation; do not use as a valid configuration type.

Note:
This enum is used to configure the USB peripheral driver behavior. It must be set before the USB stack is initialized. The value CA_USB_TYPE___MAX is intended for bounds checking and should not be assigned to a configuration variable.

Uso:
Use this type when configuring the USB subsystem in your application initialization code to tell the caOS stack which USB class driver to load and manage.

Esempio:

```
ca_usb_type_t my_usb_mode = CA_USB_TYPE_CDC;

void setup_usb(void) {
    /* Configure the USB stack to operate as a Virtual COM port */
    usb_mgmt_init(my_usb_mode);
}
```

---

ca_usb_unmounted_cb_t

Tipo: Callback
File: caos/drivers/inc/usb.h:51:51

```
typedef void (*ca_usb_unmounted_cb_t)(void)
```

A callback function pointer type triggered by the USB driver when the device is physically disconnected or logically unmounted.

Membri:

Nome	Tipo	Descrizione
void	void	The callback takes no arguments and returns nothing.

Note:
This callback is executed within the context of the USB interrupt or the USB management task. It must be kept short and non-blocking to avoid stalling the USB stack. The user is responsible for assigning a valid function address to the driver configuration structure before initializing the USB peripheral.

Uso:

Used during USB driver initialization to register a custom cleanup routine. It is typically used to update the application state machine, stop data processing tasks, or notify the user interface that the USB connection is no longer active.

Esempio:

```
void my_usb_cleanup_handler(void) { /* Reset application state */ }

/* Inside initialization code */
ca_usb_config_t config;
config.on_unmounted = my_usb_cleanup_handler;
ca_usb_init(&config);
```

---

ca_wait_queue_t

Tipo: Struttura
File: caos/inc/sync.h:34:37

```
typedef struct {
ca_thread_context_t *head;  // Points to the first task in the chain
ca_thread_context_t *tail;  // Points to the last task in the chain
} ca_wait_queue_t;
```

A wait queue structure used to manage a list of threads that are blocked waiting for a specific resource or event.

Membri:

Nome	Tipo	Descrizione
head	ca_thread_context_t *	Pointer to the first thread in the waiting list. If NULL, the queue is empty.
tail	ca_thread_context_t *	Pointer to the last thread in the waiting list. Used to efficiently append new threads to the end of the queue.

Note:
This structure must be initialized to {NULL, NULL} before use. It is typically managed by the kernel's synchronization primitives (like semaphores or mutexes). Do not manually modify these pointers unless you are implementing custom synchronization logic, as it may lead to kernel instability or thread starvation.

Uso:
Used internally by caOS synchronization objects to track threads that are in the BLOCKED state. You will encounter this when inspecting kernel objects or implementing custom blocking mechanisms.

Esempio:

```
ca_wait_queue_t my_queue = {NULL, NULL};

// Example of checking if any threads are waiting
if (my_queue.head != NULL) {
    // Threads are currently blocked on this queue
} else {
    // Queue is empty
}
```

---

ca_wdt_early_cb_t

Tipo: Callback
File: caos/drivers/inc/wdt.h:38:38

```
typedef void (*ca_wdt_early_cb_t)(void *arg)
```

A callback function type triggered by the Watchdog Timer (WDT) shortly before the system reset occurs.

Membri:

Nome	Tipo	Descrizione
arg	void *	A user-defined pointer passed to the callback when it is executed. It is typically used to pass context data or state information.

Note:
This callback is executed in an interrupt context (ISR) or a high-priority system context depending on the hardware implementation. It must be extremely fast, non-blocking, and must not perform complex operations like memory allocation or heavy I/O. The callback is registered using ca_wdt_on_early.

Uso:
Use this to perform emergency logging, save critical state to non-volatile memory, or signal other tasks that a system reset is imminent due to a watchdog timeout.

Esempio:

```
#include "caos/drivers/inc/wdt.h"

/* Emergency callback function */
void my_wdt_emergency_handler(void *arg) {
    /* Perform minimal emergency actions here */
    /* Example: Log that a WDT reset is about to happen */
    ca_printf("WDT early warning triggered!\n");
}

void setup_watchdog(void) {
    /* Register the callback to be called before WDT reset */
    /* Note: Ensure the WDT is initialized before setting the callback */
    ca_wdt_on_early(my_wdt_emergency_handler, NULL);
}
```

---

ca_wdt_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/wdt.h:30:33

```
typedef enum {
CA_WDT_MODE_RESET = 0,     /*!< MCU reset only (all families) */
CA_WDT_MODE_INTERRUPT,     /*!< Early warning interrupt + reset (if
    supported) */
} ca_wdt_mode_t;
```

Defines the behavior of the Watchdog Timer (WDT) when a timeout occurs.

Membri:

Nome	Tipo	Descrizione
CA_WDT_MODE_RESET	enum constant	The system will trigger a hardware MCU reset upon timeout. Supported by all STM32 families.
CA_WDT_MODE_INTERRUPT	enum constant	The system triggers an early warning interrupt before the reset. If the interrupt is not cleared or the WDT is not refreshed, a reset follows. Only available on specific hardware.

Note:
This enum is used during the initialization phase of the WDT driver. Ensure the hardware supports the interrupt mode before selecting CA_WDT_MODE_INTERRUPT, otherwise, the driver may default to reset or return an error.

Uso:
Pass this value to the WDT initialization function to configure the watchdog's recovery strategy. Use RESET for critical safety applications and INTERRUPT for debugging or logging purposes.

Esempio:

```
ca_wdt_config_t config = { .timeout_ms = 1000, .mode = CA_WDT_MODE_RESET };
    ca_wdt_init(&config);
```

---

ca_wdt_reset_t

Tipo: Enumerazione
File: caos/drivers/inc/wdt.h:44:48

```
typedef enum {
CA_WDT_RESET_NONE = 0,     /*!< the last reset was not a watchdog one */
CA_WDT_RESET_IWDG,         /*!< Independent Watchdog reset */
CA_WDT_RESET_WWDG,         /*!< Window Watchdog reset */
} ca_wdt_reset_t;
```

An enumeration representing the cause of the last system reset, specifically identifying if a watchdog triggered it.

Membri:

Nome	Tipo	Descrizione
CA_WDT_RESET_NONE	enum value	The system did not reset due to a watchdog; it was likely a power-on, manual reset, or software reset.
CA_WDT_RESET_IWDG	enum value	The system reset was triggered by the Independent Watchdog (IWDG).
CA_WDT_RESET_WWDG	enum value	The system reset was triggered by the Window Watchdog (WWDG).

Note:
This value is typically populated by the hardware abstraction layer during the boot process. It is read-only for the application. You should check this value early in your main() function to log or handle unexpected watchdog resets.

Uso:
Use this enum with the ca_wdt_reset_cause() function to determine why the system restarted after a crash or hang.

Esempio:

```c
#include "caos/drivers/inc/wdt.h"

void check_reset_reason(void) {
    ca_wdt_reset_t reason = ca_wdt_reset_cause();

    if (reason == CA_WDT_RESET_IWDG) {
        ca_printf("System recovered from IWDG reset!\n");
    } else if (reason == CA_WDT_RESET_WWDG) {
        ca_printf("System recovered from WWDG reset!\n");
    } else {
        ca_printf("Normal boot or non-watchdog reset.\n");
    }
}
```

---

ca_wdt_type_t

Tipo: Enumerazione
File: caos/drivers/inc/wdt.h:21:24

```c
typedef enum {
CA_WDT_TYPE_IWDG = 0,      /*!< Independent Watchdog (LSI clock) */
CA_WDT_TYPE_WWDG,          /*!< Window Watchdog (APB clock) */
} ca_wdt_type_t;
```

An enumeration defining the hardware watchdog timer peripheral type available on the STM32.

Membri:

Nome	Tipo	Descrizione
CA_WDT_TYPE_IWDG	enum constant	Independent Watchdog. Uses the internal LSI clock. Remains active even if the main system clock fails.
CA_WDT_TYPE_WWDG	enum constant	Window Watchdog. Uses the APB clock. Requires the application to refresh within a specific time window.

Note:
This enum is used to select the hardware peripheral during the initialization phase of the watchdog driver. It does not require manual allocation as it is a simple integer-based enumeration.

Uso:
Used as a parameter in the ca_wdt_init() function to specify which hardware watchdog peripheral the driver should configure and manage.

Esempio:

```c
ca_wdt_config_t config = { .type = CA_WDT_TYPE_IWDG, .timeout_ms = 1000 };
ca_wdt_init(&config);
```

Chapter 116

Reference Enumerazioni caOS

Enumerazioni globali in ordine alfabetico. Per ogni tipo: file sorgente e tabella completa degli enumeratori con il relativo valore.

`ca_aes_keysize_t`

Tipo: Enumerazione
File: `caos/crypto/inc/aes.h:34:38`

Defines the supported AES key lengths for cryptographic operations in the ca_aes_* API.

Enumeratore	Valore
`CA_AES_KEY_128`	0
`CA_AES_KEY_192`	1
`CA_AES_KEY_256`	2

Note:
The chosen key size must match the length of the key buffer provided to the ca_aes_ctx_setup function. Using an incorrect size will lead to undefined cryptographic behavior or hardware errors in the STM32 AES peripheral.

Uso:
This enum is passed as an argument to ca_aes_ctx_setup to configure the AES context before calling ca_aes_encrypt or ca_aes_decrypt.

`ca_aes_mode_t`

Tipo: Enumerazione
File: `caos/crypto/inc/aes.h:27:32`

Enumeratore	Valore
`CA_AES_MODE_ECB`	0
`CA_AES_MODE_CBC`	1
`CA_AES_MODE_CTR`	2
`CA_AES_MODE_GCM`	3

`ca_cordic_func_t`

Tipo: Enumerazione
File: `caos/drivers/inc/cordic.h:35:46`

Enumeratore	Valore
CA_CORDIC_COS	0
CA_CORDIC_SIN	*(auto)*
CA_CORDIC_PHASE	*(auto)*
CA_CORDIC_MODULUS	*(auto)*
CA_CORDIC_ATAN	*(auto)*
CA_CORDIC_COSH	*(auto)*
CA_CORDIC_SINH	*(auto)*
CA_CORDIC_ATANH	*(auto)*
CA_CORDIC_LN	*(auto)*
CA_CORDIC_SQRT	*(auto)*

---

ca_dac_comp_hyst_t

Tipo: Enumerazione
File: caos/drivers/inc/dac.h:46:51

Enumeratore	Valore
CA_DAC_COMP_HYST_NONE	0
CA_DAC_COMP_HYST_LOW	*(auto)*
CA_DAC_COMP_HYST_MEDIUM	*(auto)*
CA_DAC_COMP_HYST_HIGH	*(auto)*

---

ca_dma2d_am_t

Tipo: Enumerazione
File: caos/drivers/inc/dma2d.h:66:70

Enumeratore	Valore
CA_DMA2D_ALPHA_KEEP	0
CA_DMA2D_ALPHA_REPLACE	*(auto)*
CA_DMA2D_ALPHA_MULT	*(auto)*

---

ca_dma2d_fmt_t

Tipo: Enumerazione
File: caos/drivers/inc/dma2d.h:49:61

Enumeratore	Valore
CA_DMA2D_ARGB8888	0
CA_DMA2D_RGB888	*(auto)*
CA_DMA2D_RGB565	*(auto)*
CA_DMA2D_ARGB1555	*(auto)*
CA_DMA2D_ARGB4444	*(auto)*
CA_DMA2D_L8	*(auto)*
CA_DMA2D_AL44	*(auto)*
CA_DMA2D_AL88	*(auto)*
CA_DMA2D_L4	*(auto)*
CA_DMA2D_A8	*(auto)*
CA_DMA2D_A4	*(auto)*

`ca_dma_dir_t`

Tipo: Enumerazione
File: `caos/drivers/inc/dma.h:56:59`

Defines the direction of data transfer for DMA operations in caOS drivers.

Enumeratore	Valore
`CA_DMA_DIR_M2P`	0
`CA_DMA_DIR_P2M`	1

Note:
This enum is used to configure the DMA controller's flow direction. Choosing the wrong direction will result in data not being transferred or hardware errors. Ensure the memory address provided is valid for the chosen direction (e.g., source buffer for M2P, destination buffer for P2M).

Uso:
This type is used in ca_dma_set_request and related DMA initialization functions to define the data flow path for a specific DMA channel.

`ca_dma_width_t`

Tipo: Enumerazione
File: `caos/drivers/inc/dma.h:62:66`

Defines the data width for DMA transfer operations, used in caOS DMA configuration structures.

Enumeratore	Valore
`CA_DMA_WIDTH_8`	0
`CA_DMA_WIDTH_16`	1
`CA_DMA_WIDTH_32`	2

Note:
The width must match the destination/source register size. Mismatched widths between source and destination can lead to data corruption or hardware-level alignment faults. Ensure the memory address is aligned to the chosen width (e.g., 4-byte alignment for 32-bit transfers).

Uso:
Used in the ca_dma_config_t struct passed to ca_dma_init(). Choose the value that matches the data type of the buffer or the peripheral register being accessed.

`ca_exti_edge_t`

Tipo: Enumerazione
File: `caos/drivers/inc/exti.h:31:35`

Defines the signal transition trigger condition for external interrupts (EXTI) in the caOS driver API.

Enumeratore	Valore
`CA_EXTI_EDGE_RISING`	0
`CA_EXTI_EDGE_FALLING`	1
`CA_EXTI_EDGE_BOTH`	2

Note:

The hardware configuration depends on the specific STM32 EXTI line capabilities. Ensure the GPIO pin is correctly configured with internal pull-up or pull-down resistors if no external hardware resistor is present, otherwise the pin will float and trigger spurious interrupts.

Uso:
This enum is passed to the 'ca_exti_config' function during peripheral initialization. Choose the value based on the electrical characteristics of your input signal and the desired logic state change.

`ca_fat_event_t`

Tipo: Enumerazione
File: `caos/drivers/inc/fat_service.h:35:39`

Enumeratore	Valore
`CA_FAT_EV_MOUNTED`	`0`
`CA_FAT_EV_UNMOUNTING`	*(auto)*
`CA_FAT_EV_DESTRUCTIVE`	*(auto)*

`ca_gpio_mode_t`

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:66:71`

Defines the operational mode of an STM32 GPIO pin, used in the caOS GPIO configuration API.

Enumeratore	Valore
`CA_GPIO_MODE_INPUT`	`0`
`CA_GPIO_MODE_OUTPUT`	*(auto)*
`CA_GPIO_MODE_AF`	*(auto)*
`CA_GPIO_MODE_ANALOG`	*(auto)*

Note:
The default value is typically CA_GPIO_MODE_INPUT to ensure safety upon reset. Ensure the pin is not configured as an output if it is connected to an external voltage source to avoid short circuits. On some STM32 families, AF mode requires an additional register configuration (AFR) to select the specific peripheral mapping.

Uso:
This enum is passed to the 'gpio_init()' function. Choose the mode based on the hardware schematic: use INPUT for sensors, OUTPUT for actuators, AF for communication peripherals, and ANALOG for voltage measurement.

`ca_gpio_otype_t`

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:76:79`

Defines the output type configuration for STM32 GPIO pins, used in the GPIO initialization API.

Enumeratore	Valore
`CA_GPIO_OTYPE_PP`	`0`
`CA_GPIO_OTYPE_OD`	*(auto)*

Note:

CA_GPIO_OTYPE_PP is the default state for most GPIO pins after reset. Choosing Open-Drain without an external pull-up will result in the signal floating, which can cause unpredictable logic levels. Ensure the hardware schematic supports the chosen mode, especially for communication protocols.

Uso:
This enum is passed to the 'gpio_init' function within the GPIO configuration structure. Choose PP for general-purpose outputs and OD for communication buses or scenarios requiring wired-OR logic.

`ca_gpio_pin_t`

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:44:61`

Represents the specific physical pin index (0-15) on a GPIO port, used in all caOS GPIO configuration and control APIs.

Enumeratore	Valore
`CA_GPIO_PIN_0`	`0`
`CA_GPIO_PIN_1`	*(auto)*
`CA_GPIO_PIN_2`	*(auto)*
`CA_GPIO_PIN_3`	*(auto)*
`CA_GPIO_PIN_4`	*(auto)*
`CA_GPIO_PIN_5`	*(auto)*
`CA_GPIO_PIN_6`	*(auto)*
`CA_GPIO_PIN_7`	*(auto)*
`CA_GPIO_PIN_8`	*(auto)*
`CA_GPIO_PIN_9`	*(auto)*
`CA_GPIO_PIN_10`	*(auto)*
`CA_GPIO_PIN_11`	*(auto)*
`CA_GPIO_PIN_12`	*(auto)*
`CA_GPIO_PIN_13`	*(auto)*
`CA_GPIO_PIN_14`	*(auto)*
`CA_GPIO_PIN_15`	*(auto)*

Note:
These values correspond directly to the bit position in the STM32 GPIO IDR/ODR registers. Ensure the physical pin is not being used by the debugger (e.g., PA13/PA14) before assigning it to general logic, or you may lose connection to the board.

Uso:
Used in functions like gpio_init(), gpio_write(), and gpio_read(). Select the value based on the schematic pinout of your specific STM32 target board.

`ca_gpio_port_t`

Tipo: Enumerazione
File: `caos/drivers/inc/gpio_driver.h:27:39`

Represents the physical GPIO port identifier on the STM32 microcontroller, used in all caOS GPIO configuration and control functions.

Enumeratore	Valore
CA_GPIO_PORT_A	0
CA_GPIO_PORT_B	*(auto)*
CA_GPIO_PORT_C	*(auto)*
CA_GPIO_PORT_D	*(auto)*
CA_GPIO_PORT_E	*(auto)*
CA_GPIO_PORT_F	*(auto)*
CA_GPIO_PORT_G	*(auto)*
CA_GPIO_PORT_H	*(auto)*
CA_GPIO_PORT_I	*(auto)*
CA_GPIO_PORT_J	*(auto)*
CA_GPIO_PORT_K	*(auto)*

Note:
Not all ports are available on every STM32 chip. Attempting to configure a port that does not exist on your specific MCU will result in undefined behavior or a hard fault. Always consult the datasheet for your specific part number to confirm port availability.

Uso:
Used as the first argument in functions like caos_gpio_init(), caos_gpio_write(), and caos_gpio_read(). Choose the port based on the physical pin label found on the schematic (e.g., PA5 corresponds to CA_GPIO_PORT_A).

---

ca_gpio_pull_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:94:98

Defines the internal resistor configuration for STM32 GPIO pins, used in GPIO initialization and configuration APIs.

Enumeratore	Valore
CA_GPIO_NOPULL	0
CA_GPIO_PULLUP	*(auto)*
CA_GPIO_PULLDOWN	*(auto)*

Note:
The internal pull resistors are typically weak (approx 40k ohms). They are not a substitute for strong external resistors in high-speed communication or noisy environments. Do not enable both pull-up and pull-down simultaneously on the same pin as it may cause unexpected behavior or increased power consumption.

Uso:
This enum is passed to the 'caos_gpio_init' function within the 'GPIO_InitTypeDef' structure. Choose 'CA_GPIO_NOPULL' for standard outputs, 'CA_GPIO_PULLUP' for active-low inputs (e.g., buttons connected to GND), and 'GPIO_PULLDOWN' for active-high inputs.

---

ca_gpio_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/gpio_driver.h:84:89

Defines the output slew rate of a GPIO pin, used in the GPIO configuration API to balance signal integrity against electromagnetic interference (EMI).

Enumeratore	Valore
CA_GPIO_SPEED_LOW	0
CA_GPIO_SPEED_MED	*(auto)*
CA_GPIO_SPEED_HIGH	*(auto)*
CA_GPIO_SPEED_VERY_HIGH	*(auto)*

Note:
Higher speeds increase the risk of signal ringing and ground bounce. Always choose the lowest speed that meets your timing requirements to ensure system stability and compliance with EMC standards. The default value is typically CA_GPIO_SPEED_LOW.

Uso:
Used in the 'gpio_init_t' structure passed to 'gpio_init()'. Choose the speed based on the maximum toggle frequency of the specific pin function.

---

ca_hash_algo_t

Tipo: Enumerazione
File: caos/drivers/inc/hash.h:28:31

Defines the cryptographic hashing algorithm to be used by the caOS hardware abstraction layer for the STM32 HASH peripheral.

Enumeratore	Valore
CA_HASH_ALGO_SHA1	0
CA_HASH_ALGO_SHA256	1

Note:
The hardware peripheral must be initialized before selecting an algorithm. Switching algorithms mid-operation without resetting the HASH peripheral will result in undefined behavior. SHA-256 is significantly more computationally intensive than SHA-1, though the STM32 hardware accelerator minimizes this impact.

Uso:
This enum is passed as an argument to 'ca_hash_init()' to configure the hardware engine. Choose CA_HASH_ALGO_SHA256 for security-critical applications or CA_HASH_ALGO_SHA1 only when interfacing with existing legacy systems.

---

ca_i2c_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/i2c.h:25:28

Defines the operating clock frequency mode for the I2C peripheral in the caOS I2C driver API.

Enumeratore	Valore
CA_I2C_SPEED_STANDARD	0
CA_I2C_SPEED_FAST	1

Note:
The actual timing parameters (rise/fall times) are calculated by the driver based on the peripheral clock frequency. Ensure your pull-up resistors are sized correctly; 400 kHz requires lower resistance values than 100 kHz to avoid signal rounding.

Uso:

This enum is passed as a parameter to the ca_i2c_init() function during peripheral configuration. Choose STANDARD for general-purpose communication and FAST when the slave device supports it and bus speed is a bottleneck.

---

ca_job_type

Tipo: Enumerazione
File: caos/inc/scheduler.h:55:62

Defines the execution context and hardware resource requirements for a task, used in the ca_scheduler_add_job API.

Enumeratore	Valore
CA_JOB_STD	*(auto)*
JOB_SAFE	*(auto)*
JOB_FLOAT_POINT	*(auto)*
CA_JOB_SAFE_FLOAT_POINT	*(auto)*

Note:
Choosing a FLOAT_POINT type on an MCU without a hardware FPU will trigger a software emulation overhead, significantly slowing down the task. JOB_SAFE types consume more RAM due to the inclusion of stack guard zones. Do not use CA_JOB_STD if the task uses float variables, as the FPU registers will not be saved, leading to non-deterministic behavior.

Uso:
This enum is passed as the second argument to ca_scheduler_add_job. Choose CA_JOB_STD by default for performance, and upgrade to JOB_FLOAT_POINT only if the compiler flags indicate floating-point usage.

---

ca_jpeg_css_t

Tipo: Enumerazione
File: caos/drivers/inc/jpeg.h:45:50

Enumeratore	Valore
CA_JPEG_GRAY	0
CA_JPEG_444	*(auto)*
CA_JPEG_422	*(auto)*
CA_JPEG_420	*(auto)*

---

ca_keys_store_access_mode_t

Tipo: Enumerazione
File: caos/crypto/inc/keys_store.h:44:49

Defines the permission levels for accessing cryptographic keys stored in the caOS secure key store, used in key management APIs.

Enumeratore	Valore
CA_KEYS_STORE_NO_ACCESS	0
CA_KEYS_STORE_READ_ONLY	1
CA_KEYS_STORE_READ_WRITE	2
CA_KEYS_STORE_EXEC_ONLY	3

Note:

The default value is typically CA_KEYS_STORE_NO_ACCESS for security reasons. Once a key is set to CA_KEYS_STORE_EXEC_ONLY, it cannot be read back, meaning you must keep a secure backup if the key needs to be restored later. Changing access modes may require a system reset or specific privilege levels depending on the STM32 hardware security module (HSM) configuration.

Uso:
This enum is passed to 'keys_store_set_access()' and 'keys_store_init()' functions. Choose the most restrictive mode possible (Principle of Least Privilege) to minimize the impact of potential software vulnerabilities.

`ca_l2_result_t`

Tipo: Enumerazione
File: `caos/net/inc/net_proto.h:192:197`

Defines the packet filtering or acceptance policy for the network layer (L2) in caOS, used primarily in ca_net_proto_l2.

Enumeratore	Valore
`CA_L2_ACCEPT_UNICAST`	`0`
`CA_L2_ACCEPT_BROADCAST`	`1`
`CA_L2_ACCEPT_MULTICAST`	`2`
`CA_L2_DROP`	`3`

Note:
The default behavior depends on the network interface configuration. These values are typically used to configure hardware filters or software hooks in the network stack. Choosing CA_L2_DROP is useful for security or to reduce CPU load by ignoring irrelevant traffic early in the processing pipeline.

Uso:
This enum is used within the ca_net_proto_l2 function to determine how the network stack should handle incoming frames. When implementing a custom network filter or configuring the Ethernet controller, pass one of these values to define the acceptance policy.

`ca_lptim_mode_t`

Tipo: Enumerazione
File: `caos/drivers/inc/lptim.h:47:50`

Defines the operational behavior of the Low Power Timer (LPTIM) peripheral within the caOS hardware abstraction layer.

Enumeratore	Valore
`CA_LPTIM_MODE_PERIODIC`	`0`
`CA_LPTIM_MODE_ONESHOT`	*(auto)*

Note:
The default value is CA_LPTIM_MODE_PERIODIC. Ensure the LPTIM clock source is configured correctly in the RCC before initialization, as some modes may not be supported depending on the specific STM32 series (e.g., L0 vs U5). A common mistake is using ONESHOT mode when a continuous timebase is required for RTOS scheduling.

Uso:

This enum is passed to the ca_lptim_init() function during peripheral configuration. Choose PERIODIC for continuous background tasks and ONESHOT for transient, event-driven operations.

---

ca_opamp_input_t

Tipo: Enumerazione
File: caos/drivers/inc/opamp.h:30:33

Enumeratore	Valore
CA_OPAMP_IN_PIN	0
CA_OPAMP_IN_DAC	*(auto)*

---

ca_pwr_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/pwr.h:30:34

Defines the power consumption state for the MCU, used in the ca_pwr_enter API.

Enumeratore	Valore
CA_PWR_MODE_SLEEP	0
CA_PWR_MODE_STOP	*(auto)*
PWR_MODE_STANDBY	*(auto)*

Note:
The power modes are mutually exclusive. Choosing the wrong mode can lead to unexpected system resets (Standby) or failure to wake up if the interrupt source is disabled in that specific mode. Always ensure the required wakeup interrupt is configured before entering low power.

Uso:
This enum is passed to the ca_pwr_enter(ca_pwr_mode_t mode) function. Select the mode based on the required balance between power consumption and wakeup latency.

---

ca_qspi_pin_t

Tipo: Enumerazione
File: caos/drivers/inc/qspi.h:147:150

Enumeratore	Valore
CA_QSPI_PIN_CLK	0, CA_QSPI_PIN_NCS, CA_QSPI_PIN_IO0

---

ca_rtc_clk_src_t

Tipo: Enumerazione
File: caos/drivers/inc/rtc.h:32:37

Defines the clock source for the RTC peripheral in the caOS RTC driver API.

Enumeratore	Valore
CA_RTC_CLK_AUTO	0
CA_RTC_CLK_LSE	1
CA_RTC_CLK_LSI	2
CA_RTC_CLK_HSE	3

Note:

The clock source must be configured before the RTC is initialized. Changing the clock source while the RTC is running may lead to undefined behavior or loss of time data. Ensure the corresponding oscillator is enabled in the system clock configuration before selecting it here.

Uso:
This enum is passed to the ca_rtc_init() function. Choose CA_RTC_CLK_LSE for production devices requiring accurate timekeeping, and CA_RTC_CLK_LSI for low-cost prototypes without an external crystal.

`ca_sai_proto_t`

Tipo: Enumerazione
File: `caos/drivers/inc/sai.h:60:64`

Enumeratore	Valore
`CA_SAI_I2S`	`0`
`CA_SAI_MSB`	*(auto)*
`CA_SAI_SPDIF`	*(auto)*

`ca_scheduler_tasks_info_mode`

Tipo: Enumerazione
File: `caos/inc/scheduler.h:427:433`

Defines the level of detail and data source for task information retrieval in the caOS scheduler API.

Enumeratore	Valore
`CA_TH_INFO_DEFAULT`	`0`
`CA_TH_INFO_FLAG`	*(auto)*
`TH_INFO_RUNTIME`	*(auto)*
`CA_TH_INFO_MEM`	*(auto)*
`TH_INFO_ASSERT`	*(auto)*

Note:
CA_TH_INFO_DEFAULT is the fallback mode if an invalid value is passed. These modes are mutually exclusive; you can only request one type of information per function call. Note that TH_INFO_RUNTIME requires the scheduler's runtime statistics feature to be enabled in the configuration file, otherwise it may return zeroed data.

Uso:
This enum is used as an argument in the 'ca_scheduler_get_task_info' function. Choose the mode based on the specific diagnostic data required: use DEFAULT for general status, MEM for stack analysis, or RUNTIME for performance tuning.

`ca_secure_pipe_end_t`

Tipo: Enumerazione
File: `caos/crypto/inc/secure_pipe_service.h:39:42`

Enumeratore	Valore
`CA_SECURE_PIPE_A`	`0U`
`CA_SECURE_PIPE_B`	`1U`

---

ca_spi_br_t

Tipo: Enumerazione
File: caos/drivers/inc/spi.h:45:54

Defines the SPI baud rate prescaler relative to the peripheral clock, used in ca_spi_init() to configure communication speed.

Enumeratore	Valore
CA_SPI_BR_DIV2	0
CA_SPI_BR_DIV4	1
CA_SPI_BR_DIV8	2
CA_SPI_BR_DIV16	3
CA_SPI_BR_DIV32	4
CA_SPI_BR_DIV64	5
CA_SPI_BR_DIV128	6
CA_SPI_BR_DIV256	7

Note:
The actual frequency depends on the clock source of the specific SPI bus (e.g., APB1 or APB2). Ensure the resulting frequency does not exceed the maximum clock speed specified in the datasheet of the connected slave device. Choosing a value that is too high will result in data corruption or failed communication.

Uso:
This enum is passed as a member of the configuration structure to the ca_spi_init() function. Select the highest value that remains within the slave device's maximum clock frequency specification.

---

ca_stack_size_t

Tipo: Enumerazione
File: hw/f1xx/f103/objmap.h:51:58

Defines predefined memory allocation sizes for task stacks within the caOS RTOS, used during task creation APIs.

Enumeratore	Valore
STACK_SMALL	(STACK_MIN*2)
STACK_MEDIUM	(STACK_SMALL*2)
STACK_LARGE	(STACK_MEDIUM)
STACK_XLARGE	(STACK_MEDIUM)
STACK_KERNEL	(STACK_MEDIUM)

Note:
On the STM32F103, stack sizes are defined in bytes. Note that STACK_LARGE, STACK_KERNEL, and STACK_XLARGE are currently aliases for STACK_MEDIUM. Choosing a size too small will result in a stack overflow, which typically triggers a HardFault exception. Always monitor stack usage using the caOS debug tools.

Uso:
Used as an argument in task creation functions like 'caos_task_create()'. Choose based on the task's complexity: start with STACK_MEDIUM and reduce to STACK_SMALL if memory is tight, or increase if you encounter stack overflow errors.

`ca_sw_timer_mode_t`

Tipo: Enumerazione
File: `caos/inc/sw_timer.h:55:58`

Defines the execution behavior of a software timer within the caOS RTOS timer management API.

Enumeratore	Valore
`CA_TIMER_ONE_SHOT`	`0`
`CA_TIMER_PERIODIC`	`1`

Note:
The timer mode is set during the creation phase and cannot be changed while the timer is running. Choosing CA_TIMER_PERIODIC requires careful management of the callback execution time to ensure it does not exceed the timer period, which could lead to missed intervals or system instability.

Uso:
This enum is used as an argument in the ca_sw_timer_create() function. Choose CA_TIMER_ONE_SHOT for tasks like delayed power-off or debouncing, and CA_TIMER_PERIODIC for recurring tasks like status polling or heartbeat signals.

`ca_sw_timer_state_t`

Tipo: Enumerazione
File: `caos/inc/sw_timer.h:61:65`

Represents the current operational state of a software timer within the caOS RTOS timer management API.

Enumeratore	Valore
`CA_TIMER_STOPPED`	`0`
`CA_TIMER_RUNNING`	`1`
`CA_TIMER_EXPIRED`	`2`

Note:
The state is managed internally by the caOS kernel. Manually forcing these values via pointers is discouraged as it may lead to race conditions or inconsistent timer queue processing. CA_TIMER_STOPPED is the default state upon timer initialization.

Uso:
Used in ca_sw_timer_get_state() to query the status of a timer handle and internally by the scheduler to determine if a timer callback should be executed.

`ca_tick_speed_t`

Tipo: Enumerazione
File: `caos/inc/systick.h:35:46`

Defines the system tick interval in microseconds, used in the caOS initialization API to configure the SysTick timer frequency.

Enumeratore	Valore
CA_TICK_SPEED_100US	100
CA_TICK_SPEED_200US	200
CA_TICK_SPEED_250US	250
CA_TICK_SPEED_400US	400
CA_TICK_SPEED_500US	500
CA_TICK_SPEED_1MS	1000
CA_TICK_SPEED_2MS	2000
CA_TICK_SPEED_4MS	4000
CA_TICK_SPEED_5MS	5000
CA_TICK_SPEED_10MS	10000

Note:
The tick speed determines the resolution of all OS delays and timeouts. Choosing a value that is too small (e.g., 100us) on low-clock-speed MCUs can lead to 'tick starvation' where the CPU spends most of its time in the SysTick ISR. This value must be set once during system boot and cannot be changed at runtime.

Uso:
Passed as an argument to the 'caos_init()' or 'caos_systick_config()' functions. Choose the largest value that still satisfies the timing requirements of your most time-critical task.

`ca_timer_ic_src_t`

Tipo: Enumerazione
File: `caos/drivers/inc/timer.h:58:62`

Enumeratore	Valore
CA_TIMER_IC_PIN	0
CA_TIMER_IC_LSE	*(auto)*
CA_TIMER_IC_LSI	*(auto)*

`ca_timer_mode_t`

Tipo: Enumerazione
File: `caos/drivers/inc/timer.h:43:51`

Defines the operational mode of a hardware timer peripheral within the caOS timer driver API.

Enumeratore	Valore
CA_TIMER_MODE_PERIODIC	0
CA_TIMER_MODE_ONESHOT	*(auto)*
TIMER_MODE_COUNTER	*(auto)*
CA_TIMER_MODE_ENCODER	*(auto)*
TIMER_MODE_COUNTER_IRQ	*(auto)*
CA_TIMER_MODE_PWM	*(auto)*
CA_TIMER_MODE_CAPTURE	*(auto)*

Note:
CA_TIMER_MODE_PERIODIC is the default value. Ensure the timer peripheral supports the selected mode, as some basic timers (e.g., TIM6/TIM7 on STM32) do not support PWM or Encoder modes. Avoid changing modes while the timer is running; always stop the timer before reconfiguring.

Uso:

Used in the ca_timer_init() function. Choose the mode based on your hardware requirement: use PERIODIC for timing, PWM for power control, and ENCODER for motion feedback.

---

ca_uart_baud_rate_t

Tipo: Enumerazione
File: caos/drivers/inc/uart.h:30:45

Defines the supported communication speeds for UART peripherals in the caOS driver API.

Enumeratore	Valore
CA_UART_BAUD_9600	9600
CA_UART_BAUD_19200	19200
CA_UART_BAUD_38400	38400
CA_UART_BAUD_57600	57600
CA_UART_BAUD_115200	115200
CA_UART_BAUD_230400	230400
CA_UART_BAUD_460800	460800
CA_UART_BAUD_921600	921600
CA_UART_BAUD_1000000	1000000
CA_UART_BAUD_2000000	2000000
CA_UART_BAUD_3000000	3000000
CA_UART_BAUD_4000000	4000000
CA_UART_BAUD_4500000	4500000
CA_UART_BAUD_5000000	5000000

Note:
The actual baud rate error depends on the STM32 peripheral clock frequency. Always check the calculated baud rate error in the datasheet for your specific MCU. High baud rates (>1 Mbps) are highly sensitive to cable length and capacitance. DMA is strongly recommended for baud rates above 115200 to avoid CPU starvation.

Uso:
Used in the uart_init() function to configure the hardware baud rate generator. Select the value based on the requirements of the connected peripheral device.

---

ca_usb_ep_type_t

Tipo: Enumerazione
File: caos/drivers/inc/usb.h:37:42

Enumeratore	Valore
CA_USB_EP_TYPE_CTRL	0
CA_USB_EP_TYPE_ISOC	1
CA_USB_EP_TYPE_BULK	2
CA_USB_EP_TYPE_INTR	3

---

ca_usb_speed_t

Tipo: Enumerazione
File: caos/drivers/inc/usb.h:44:47

Defines the operational speed mode for the USB peripheral, used in the caOS USB initialization and configuration API.

Enumeratore	Valore
CA_USB_SPEED_FS	0
CA_USB_SPEED_HS	1

Note:
The default value is typically CA_USB_SPEED_FS. Not all STM32 MCUs support High-Speed; attempting to set CA_USB_SPEED_HS on a device without an integrated or external HS PHY will result in initialization failure. Ensure the system clock configuration (HSE/PLL) is sufficient to support the chosen speed, especially for HS.

Uso:
This enum is passed to the ca_usb_init() function. Choose CA_USB_SPEED_FS for general-purpose connectivity or CA_USB_SPEED_HS only if your hardware design explicitly includes a High-Speed PHY and you require higher throughput.

---

ca_usb_type_t

Tipo: Enumerazione
File: caos/usb/inc/usb_mgmt.h:43:51

Defines the USB device class configuration for the caOS USB management stack, used during initialization to determine the device's functional role.

Enumeratore	Valore
CA_USB_TYPE_NONE	0
CA_USB_TYPE_CDC	1
CA_USB_TYPE_MSC	2
CA_USB_TYPE_NCM	3
CA_USB_TYPE_DFU	4
CA_USB_TYPE_CUSTOM	5
CA_USB_TYPE__MAX	*(auto)*

Note:
The default value is CA_USB_TYPE_NONE. These values are mutually exclusive; only one USB class can be active per instance. Ensure the hardware descriptors match the selected type, as selecting an incorrect type will cause enumeration failure on the host PC.

Uso:
This enum is passed to the ca_usb_init() function. Choose the value based on the desired communication protocol required by your project specifications.

---

ca_wdt_mode_t

Tipo: Enumerazione
File: caos/drivers/inc/wdt.h:32:35

Defines the watchdog timer behavior upon timeout, used in the caOS WDT driver initialization API.

Enumeratore	Valore
CA_WDT_MODE_RESET	0
CA_WDT_MODE_INTERRUPT	*(auto)*

Note:
CA_WDT_MODE_RESET is the default and safest choice for production firmware. CA_WDT_MODE_INT should be used with caution as it does not guarantee system recovery if the CPU is stuck in a

hard fault or critical error state. Ensure the watchdog is refreshed (kicked) frequently enough to avoid unintended resets.

Uso:
This enum is passed to the 'ca_wdt_init()' function. Choose CA_WDT_MODE_RESET for standard watchdog functionality. Choose CA_WDT_MODE_INTERRUPT only during development phases when you need to inspect the system state via a breakpoint or log before the watchdog forces a reset.

`ca_wdt_reset_t`

Tipo: Enumerazione
File: `caos/drivers/inc/wdt.h:44:48`

Enumeratore	Valore
`CA_WDT_RESET_NONE`	`0`
`CA_WDT_RESET_IWDG`	*(auto)*
`CA_WDT_RESET_WWDG`	*(auto)*

`ca_wdt_type_t`

Tipo: Enumerazione
File: `caos/drivers/inc/wdt.h:23:26`

Defines the hardware watchdog timer peripheral type used in the caOS WDT driver API.

Enumeratore	Valore
`CA_WDT_TYPE_IWDG`	`0`
`CA_WDT_TYPE_WWDG`	*(auto)*

Note:
IWDG is independent of the system clock and is the safest choice for general system hang recovery. WWDG is more precise but will stop if the system clock fails or enters certain low-power modes. Do not attempt to refresh a WWDG too early, as it will trigger a reset if the counter is above the window threshold.

Uso:
Used in 'ca_wdt_init()' to configure the hardware peripheral. Choose IWDG for long-term system stability and WWDG for strict timing-sensitive task monitoring.

Chapter 117

Reference Definizioni caOS

Costanti e flag di configurazione in ordine alfabetico. Per ogni voce: valore per MCU, descrizione, note d'uso.

`AES_CH_HDR_SIZE`

File: `caos/crypto/inc/aes_channel_service.h`

Defines the total size of the header used in AES channel communication packets.

Valore: `(AES_CH_IV_SIZE + 2U)`

Note:
This constant represents the sum of the Initialization Vector (IV) size and an additional 2-byte overhead. It is used to calculate buffer offsets for encrypted data streams. It depends directly on AES_CH_IV_SIZE. Changing this value will break compatibility with existing encrypted communication protocols if not updated on both sender and receiver sides.

Uso:
Do not modify this value unless you are changing the underlying cryptographic protocol specification. If you encounter buffer overflow errors during decryption or encryption, verify that your allocated buffers account for this header size plus the payload size.

`AES_CH_IV_SIZE`

File: `caos/crypto/inc/aes_channel_service.h`

Defines the fixed size in bytes for the Initialization Vector (IV) used in AES channel encryption.

Valore: `12U`

Note:
This constant sets the buffer length for the IV required by the AES-GCM or AES-CTR modes. Changing this value affects the memory allocation of the AES channel control blocks. It must match the hardware-accelerated AES peripheral requirements of the STM32 series being used; typical values are 12 bytes for GCM or 16 bytes for CBC/CTR modes.

Uso:
Modify this only if the underlying cryptographic standard or hardware security module (HSM) requirements change. Setting an incorrect value will cause encryption/decryption failures or buffer overflows. Ensure all communicating nodes are configured with the same IV size to maintain protocol compatibility.

AES_CH_OVERHEAD

File: caos/crypto/inc/aes_channel_service.h

Defines the total byte overhead added to each encrypted data packet for metadata storage.

Valore: (AES_CH_IV_SIZE + 2U + AES_CH_TAG_SIZE)

Note:
This constant represents the sum of the Initialization Vector (IV), a 2-byte header, and the authentication tag size. Increasing this value consumes more RAM per channel buffer and reduces the effective payload capacity of each transmission. It must be consistent across all communicating nodes to prevent decryption failures.

Uso:
Adjust this value only if the underlying AES security parameters (like IV length or tag size) are modified in the system configuration. Incorrect values will lead to buffer overflows or data corruption during packet parsing. Ensure that the resulting total overhead does not exceed the maximum MTU of your communication interface.

AES_CH_TAG_SIZE

File: caos/crypto/inc/aes_channel_service.h

Defines the byte length of the authentication tag used for AES-GCM cryptographic operations.

Valore: AES_GCM_TAG_SIZE

Note:
This constant sets the size of the integrity check value appended to encrypted data. It must match the tag size expected by the receiver. Typical values are 16 bytes (128 bits) for maximum security, though 8 or 12 bytes are sometimes used for bandwidth-constrained applications. It depends on the underlying hardware crypto peripheral capabilities and the specific GCM implementation settings.

Uso:
Change this value only if your security protocol or communication partner requires a non-standard tag length. Using a smaller tag size reduces packet overhead but significantly increases the risk of forgery attacks. Ensure that the value is consistent across all communicating nodes, as a mismatch will cause authentication failures and dropped packets.

AES_GCM_TAG_SIZE

File: caos/drivers/inc/aes.h

Defines the length in bytes of the authentication tag generated or verified by the AES-GCM cryptographic algorithm.

Valore: 16

Note:
The value 16 corresponds to 128 bits, which is the standard and maximum tag size for AES-GCM. Reducing this value decreases security by increasing the probability of tag forgery. This constant must match the tag size expected by the remote peer or the stored encrypted data; otherwise, decryption will fail with an authentication error.

Uso:
Keep this set to 16 for all standard security applications. Only modify this value if you are interfacing with a legacy system or a specific protocol that explicitly requires truncated tags (e.g., 8 or 12 bytes). Changing this value requires a full recompile of all modules utilizing the AES driver.

`ARP_CACHE_SIZE`

File: `os_config.h`

Defines the maximum number of IP-to-MAC address mappings stored in the ARP cache table.

Valore: `8U`

Note:
Increasing this value allows the system to track more network devices simultaneously but consumes more RAM. Each entry typically occupies a fixed structure size. If the cache is full, the oldest entry is usually overwritten. Valid range is typically 4 to 32 depending on available heap memory.

Uso:
Increase this value if your device communicates with many different IP addresses on the local network to prevent frequent ARP requests. Decrease it to save RAM if your device only communicates with a single gateway or a very small number of static peers.

`ARP_ENTRY_TTL`

File: `os_config.h`

Defines the Time-To-Live (TTL) duration in milliseconds for entries stored in the ARP cache.

Valore: `30000U`

Note:
This constant determines how long an IP-to-MAC address mapping remains valid before being discarded or refreshed. The value is expressed in milliseconds; 30000U equals 30 seconds. Increasing this value reduces network traffic by minimizing ARP requests but may lead to stale entries if devices change their MAC addresses frequently. Decreasing it ensures higher accuracy but increases broadcast traffic on the local network.

Uso:
Adjust this value if your device operates in a dynamic network environment where IP/MAC mappings change often, or if you need to optimize bandwidth usage. Set a lower value (e.g., 5000U) for highly dynamic networks or a higher value (e.g., 60000U) for static, low-power environments. Ensure the value is not set too low to avoid excessive ARP request storms.

`ARP_HTYPE_ETH`

File: `caos/net/inc/net_proto.h`

Defines the hardware type identifier for Ethernet networks within the ARP protocol stack.

Valore: `1U`

Note:

This constant is set to 1U, which is the standard IANA-assigned value for Ethernet (10Mb). It is used in the hardware type field of ARP packets. Changing this value will cause the network stack to fail to communicate with standard Ethernet hardware, as the remote host will reject the ARP request as an unsupported protocol type.

Uso:
This value should generally not be changed for standard STM32 Ethernet implementations. It is used by the caOS network driver to identify the physical medium. Only modify this if you are implementing a custom non-Ethernet link layer that still requires ARP-like address resolution.

`ARP_OP_REPLY`

File: `caos/net/inc/net_proto.h`

Defines the ARP operation code for an ARP Reply packet.

Valore: `2U`

Note:
This constant represents the integer value 2, which identifies an incoming or outgoing packet as an ARP Reply in the Ethernet frame header. It is a fixed protocol value defined by RFC 826 and must not be modified. It is typically used in the network stack's packet parsing logic to distinguish replies from requests (ARP_OP_REQUEST, value 1).

Uso:
Use this constant when writing custom packet filtering or network diagnostic tools to identify ARP replies. Do not change this value, as it is strictly defined by the ARP protocol standard; changing it will cause the network stack to fail to recognize legitimate ARP responses, leading to a loss of connectivity.

`ARP_OP_REQUEST`

File: `caos/net/inc/net_proto.h`

Defines the operation code for an ARP Request packet in the network stack.

Valore: `1U`

Note:
This constant represents the ARP opcode 1, which signals a request for a hardware address. It is used by the network stack to construct outgoing ARP packets. It has no dependencies on other flags but must match the standard ARP protocol specification (RFC 826).

Uso:
This value should generally not be changed as it is a protocol-defined constant. It is used when the system needs to resolve an IP address to a MAC address. Modifying this value will cause the network stack to send invalid ARP packets, resulting in a failure to communicate with other devices on the local network.

`ARP_PTYPE_IP`

File: `caos/net/inc/net_proto.h`

Defines the Ethernet frame type identifier for the IPv4 protocol.

Valore: `0x0800U`

Note:
This constant represents the hexadecimal value 0x0800, which is the standard EtherType for IPv4 packets as defined by IEEE 802.3. It is used by the caOS network stack to filter incoming Ethernet frames and identify which packets should be passed to the IP layer. Changing this value will cause the device to ignore all standard IPv4 traffic.

Uso:
This value should generally remain unchanged as it follows the global networking standard. You would only modify this if you are implementing a custom, non-standard network protocol or working in a specialized environment that does not use standard IPv4 encapsulation. Ensure this matches the hardware-level frame filtering settings if your STM32 Ethernet peripheral is configured to perform hardware-based packet filtering.

`ARP_RETRY_MS`

File: `os_config.h`

Defines the timeout duration in milliseconds for the ARP protocol to wait before retransmitting an address resolution request.

Valore: `500U`

Note:
This value directly impacts the latency of network communication when a MAC address is unknown. Increasing this value reduces network traffic but slows down connection establishment; decreasing it speeds up recovery but may cause network congestion. It must be a positive integer, typically ranging from 100 to 2000 depending on the network stability.

Uso:
Adjust this value if your device experiences connection timeouts on busy or high-latency networks. If you notice the device failing to resolve IP addresses, try increasing this value. Ensure it is not set too low, as frequent retries can overwhelm the network stack and lead to packet loss.

`ARP_RETRY_N`

File: `os_config.h`

Defines the maximum number of times the ARP protocol will retransmit an address resolution request before giving up.

Valore: `3U`

Note:
When enabled, the system will attempt to resolve a MAC address for a given IP up to this count. If the target device does not respond after these attempts, the network stack will return an error. Typical values range from 1 to 5. Increasing this value improves reliability on lossy networks but increases latency during connection failures.

Uso:
Increase this value if you experience intermittent connection drops or if the network environment has high packet loss. Decrease it if you need the system to fail fast and report network errors quickly to the application layer. Setting this to 0 may prevent the system from ever resolving addresses.

ARRAY_SIZE

File: caos/inc/common.h

A macro that calculates the total number of elements in a static array.

Valore: (sizeof(arr) / sizeof((arr)[0]))

Note:
This macro divides the total memory size of the array by the size of a single element. It only works on arrays defined in the current scope; it will fail if passed a pointer to an array, as the pointer size will be used instead of the array size. It is a compile-time calculation with no runtime overhead.

Uso:
Use this whenever you need to iterate through an array or define buffer limits to avoid hardcoding magic numbers. Always ensure the input is a true array and not a pointer to prevent incorrect size calculations and potential buffer overflows.

CAOS_ENDIAN_BIG

File: caos/inc/endian.h

Defines the byte order (endianness) of the processor architecture, where 0 indicates Little-Endian.

Valore: 0

Note:
When set to 0, the system treats the least significant byte as the first byte in memory. STM32 microcontrollers (ARM Cortex-M) are natively Little-Endian, so this must remain 0 for standard operation. Setting this to 1 on an STM32 will cause data corruption during memory access and network communication.

Uso:
Keep this value at 0 for all STM32-based projects. Only change this if porting caOS to a Big-Endian architecture (e.g., certain PowerPC or older legacy processors). Incorrect configuration will result in swapped bytes in multi-byte variables like integers and pointers.

CAOS_ENDIAN_LITTLE

File: caos/inc/endian.h

Defines the byte order (endianness) of the processor architecture as Little-Endian.

Valore: 1

Note:
When set to 1, the system treats the least significant byte as the first byte in memory. This flag is typically required for ARM Cortex-M processors used in STM32 devices. Disabling this (setting to 0) will cause data corruption during memory access, network packet parsing, and peripheral register operations.

Uso:
This value should almost always remain set to 1 for STM32 development. Only change this if you are porting caOS to a specific Big-Endian architecture, which is rare in the STM32 ecosystem. Incorrect configuration will lead to unpredictable system behavior and invalid data processing.

CA_BOOT_BKP_MSG

File: caos/inc/boot_image.h

Defines the specific index or ID used for storing boot-related status messages in the backup register/SRAM area.

Valore: 17U

Note:
This constant acts as an offset or identifier for the ca_bkp_* API functions. It determines which memory slot in the non-volatile backup domain is reserved for boot diagnostic messages. It is typically used during the bootloader sequence to persist error codes or status flags across system resets. The value 17U is a fixed hardware-specific mapping.

Uso:
Do not change this value unless the memory map of the backup domain is redefined. It is used as an argument for ca_bkp_write or ca_bkp_read to ensure the bootloader and the application are accessing the same memory location for status reporting. Incorrect values will lead to reading garbage data or overwriting critical system configuration stored in other backup registers.

CA_BOOT_BKP_STATE

File: caos/inc/boot_image.h

Defines the specific backup register index used by the bootloader to store the system state.

Valore: 16U

Note:
This constant specifies the hardware backup register (BKP) index on the STM32. It is used by the bootloader to persist state information across system resets. Changing this value requires ensuring the index does not conflict with other system-level data stored in the backup domain. Valid range is typically 0 to 41, depending on the specific STM32 series.

Uso:
Change this value only if the current backup register index conflicts with other firmware components or hardware peripherals using the backup domain. Ensure that the new index is correctly mapped in the hardware documentation for your specific STM32 chip. Incorrect values may lead to boot loops or failure to recover the system state after a reset.

CA_BOOT_CONFIRMED

File: caos/inc/boot_image.h

A magic constant used to mark a firmware update image as successfully verified and ready for permanent execution.

Valore: 0xFFU

Note:
This value is typically written to a specific flash memory location or metadata header. When the bootloader checks this location, it compares the stored value against CA_BOOT_CONFIRMED (0xFFU). If they match, the system considers the update 'confirmed'. If the value is different (e.g., 0x00U), the system may trigger a rollback or enter a recovery mode. It is a fundamental part of the caOS A/B update mechanism.

Uso:
Use this constant when calling ca_boot_confirm() to finalize a firmware update process. You should only call this function after your application has performed its own self-tests (e.g., checking network connectivity or sensor data) to ensure the new firmware is stable. Warning: Never write this value to the confirmation slot before the application is fully verified, as doing so prevents the system from automatically rolling back to the previous known-good firmware in case of a crash.

`CA_BOOT_HDR_SIZE`

File: `caos/inc/boot_image.h`

Defines the fixed size in bytes reserved for the bootloader header at the start of a firmware image.

Valore: `0x400U`

Note:
This constant determines the offset where the actual application code begins within the flash memory slot. It must match the value used by the bootloader to parse the image metadata. Changing this value requires re-linking the application and updating the bootloader configuration. The value 0x400U (1024 bytes) is the standard alignment for caOS boot images.

Uso:
Change this value only if the bootloader header structure is modified to include more metadata (e.g., larger digital signatures or additional configuration fields). Warning: If this value does not match the bootloader's expectation, the system will fail to verify or boot the application, potentially resulting in a bricked state requiring a manual flash via JTAG/SWD.

`CA_BOOT_IWDG_MS`

File: `caos/inc/boot_image.h`

Defines the Independent Watchdog (IWDG) timeout duration in milliseconds during the boot sequence.

Valore: `8000U`

Note:
This constant sets the hardware watchdog period before the RTOS scheduler takes over. If the system does not reach the application initialization phase and reload the watchdog within this time, the STM32 will trigger a hardware reset. The value is in milliseconds (8000U = 8 seconds). It depends on the hardware IWDG clock configuration.

Uso:
Increase this value if the boot process (e.g., flash integrity checks, network initialization, or filesystem mounting) takes longer than 8 seconds to avoid spurious resets. Decrease it if you require a faster system recovery time in case of a hang during the early boot stage. Ensure the value does not exceed the maximum hardware timeout supported by the STM32 IWDG peripheral.

CA_BOOT_LOADER_LEN

File: caos/inc/boot_image.h

Defines the total memory size reserved for the bootloader image in the flash memory.

Valore: 0x00080000U

Note:
This constant sets the boundary for the bootloader section. It is typically used by the memory map and the bootloader update logic to ensure that application images do not overwrite the bootloader code. The value 0x00080000U represents 512 KB. Changing this requires a corresponding update to the linker script (.ld file) to ensure the memory regions are aligned with this constant.

Uso:
Change this value only if you are modifying the flash memory layout or if the bootloader code size exceeds the current allocation. Incorrect values will lead to memory corruption, boot failures, or the application overwriting critical bootloader code. Always verify the flash sector boundaries of your specific STM32 microcontroller before adjusting this value.

CA_BOOT_MAGIC

File: caos/inc/boot_image.h

A unique 32-bit identifier used to verify the integrity and validity of a firmware boot image.

Valore: 0xCAB70000U

Note:
This constant is typically placed at the beginning of a firmware binary or a specific header structure. The bootloader checks this magic value before attempting to execute the image. If the value does not match 0xCAB70000U, the bootloader will reject the image as corrupted or incompatible. It is a static constant and should not be modified at runtime.

Uso:
Use this constant when defining the header structure for your firmware images to ensure the bootloader only runs valid caOS-compatible code. If you change this value, you must update both the bootloader's verification logic and the build script that generates the firmware header, otherwise, the device will fail to boot after an update.

CA_BOOT_MAGIC_MASK

File: caos/inc/boot_image.h

A bitmask used to validate the integrity and authenticity of a firmware image header during the boot process.

Valore: 0xFFFF0000U

Note:
This constant defines the upper 16 bits of a 32-bit magic word. When the bootloader inspects a firmware image, it performs a bitwise AND operation with this mask to verify that the header contains the expected signature. If the result does not match the expected magic value, the bootloader will reject the image as invalid or corrupted. It is typically used in conjunction with a lower 16-bit version or status field.

Uso:
Change this value only if you are modifying the bootloader's image verification protocol or creating a new firmware format. Incorrect values will cause the system to fail to boot any firmware, potentially bricking the device until a valid image is flashed via a hardware debug interface (e.g., JTAG/SWD). Ensure this matches the value defined in your firmware build tools.

`CA_BOOT_MAX_TRIES`

File: `caos/inc/boot_image.h`

Defines the maximum number of boot attempts allowed for a firmware image before marking it as invalid.

Valore: `3U`

Note:
This constant controls the retry logic during the boot sequence. If the system fails to boot (e.g., due to a crash or watchdog reset) after this many attempts, the bootloader will typically revert to a previous stable image or enter a recovery state. It is a critical safety mechanism to prevent boot loops. Typical values range from 1 to 5.

Uso:
Increase this value if your application has a complex initialization sequence that might occasionally trigger a watchdog reset during legitimate startup. Decrease it if you want the system to fail over to a recovery image more aggressively. Do not set this to 0, as it would prevent any boot attempts.

`CA_BOOT_MSG`

File: `caos/inc/boot_image.h`

Constructs a unique boot message identifier for the caOS bootloader system.

Valore: `(CA_BOOT_MAGIC | ((u32)(u8)(cmd) « 8) | (u32)(u8)(slot))`

Note:
This macro combines a magic constant (CA_BOOT_MAGIC), a command code, and a target slot index into a single 32-bit value. It is used to communicate boot instructions between the application and the bootloader. The command is shifted by 8 bits, and the slot index occupies the lowest 8 bits. Ensure that 'cmd' and 'slot' are cast to u8 to prevent overflow into the magic constant bits.

Uso:
Use this macro when calling ca_boot_request_update or similar bootloader interface functions to specify which firmware slot to target and what action to perform. Do not modify the structure of this macro, as the bootloader expects this exact bit-packed format to validate the request.

`CA_BOOT_MSG_UPDATE`

File: `caos/inc/boot_image.h`

Defines the character identifier used in the bootloader to signal that a firmware update is available.

Valore: `'U'`

Note:
This constant is typically used as a command byte or status flag within the bootloader communication protocol. When the bootloader receives this specific character, it triggers the update sequence. It is a single-byte constant ('U'). Changing this value requires updating both the sender (e.g., a PC-side tool or another MCU) and the receiver (the caOS bootloader) to ensure they use the same handshake protocol.

Uso:
Change this value only if you need to modify the communication protocol between the bootloader and the host. Ensure that the host software is updated to send the new character, otherwise, the bootloader will fail to recognize the update request. Incorrect values will result in the system ignoring update commands, effectively locking the device in its current firmware version.

`CA_BOOT_SLOT_A_BASE`

File: `caos/inc/boot_image.h`

Defines the starting memory address for the primary application firmware slot (Slot A) in Flash.

Valore: `(0x08000000U + CA_BOOT_LOADER_LEN)`

Note:
This constant calculates the absolute memory address by adding the bootloader size (CA_BOOT_LOADER_L
to the base Flash address (0x08000000U). It is used by the bootloader and the application update system to locate where the executable code for Slot A begins. Changing this value requires a corresponding update to the linker script (.ld file) to ensure the application is compiled for the correct memory offset.

Uso:
Modify this value only when changing the size of the bootloader or repartitioning the Flash memory layout. Incorrect values will cause the system to jump to an invalid memory location, resulting in a hard fault or a failure to boot the application. Always ensure that the resulting address is aligned with the Flash sector boundaries of the specific STM32 microcontroller being used.

`CA_BOOT_SLOT_B_BASE`

File: `caos/inc/boot_image.h`

Defines the starting memory address for the secondary firmware image (Slot B) in the flash memory.

Valore: `0x08100000U`

Note:
This constant represents the absolute physical address in the STM32 internal flash where the secondary firmware image is stored. It is used by the bootloader to locate and verify the update image. It must be aligned with the flash sector boundaries defined in the hardware datasheet. Changing this value requires a corresponding update to the linker script (.ld file) to ensure the application is compiled for the correct memory region.

Uso:

Modify this value only when changing the flash memory layout or partition scheme. Incorrect values will cause the bootloader to fail to locate or boot the secondary image, potentially bricking the device if the primary image is also corrupted. Always ensure the address does not overlap with the primary image (Slot A) or the bootloader code itself.

`CA_BOOT_SLOT_LEN`

File: `caos/inc/boot_image.h`

Defines the fixed size in bytes allocated for each firmware update slot in the flash memory.

Valore: `0x00080000U`

Note:
This constant determines the maximum capacity of a single firmware image slot. It must be a multiple of the flash sector size to ensure proper erasure. If the application binary exceeds this size, the bootloader will reject the update. Typical values are powers of two (e.g., 0x80000 for 512KB).

Uso:
Change this value only when modifying the flash memory map or when the application binary size grows beyond the current limit. Ensure that the total flash size of the STM32 device can accommodate the number of slots defined in the system (e.g., Slot A + Slot B + Bootloader) without overlapping.

`CA_BOOT_STATE`

File: `caos/inc/boot_image.h`

A packed 32-bit value representing the boot configuration, including the target firmware slot and retry count.

Valore: `(CA_BOOT_MAGIC | ((u32)(u8)(slot) « 8) | ((u32)(tries) & 0xFFU))`

Note:
The constant is composed of a magic number (bits 31-16), the target firmware slot index (bits 15-8), and the remaining boot retry attempts (bits 7-0). It is typically stored in non-volatile memory (e.g., backup registers) to inform the bootloader which firmware image to execute after a reset. It depends on the CA_BOOT_MAGIC constant being defined in the system configuration.

Uso:
Use this when implementing custom bootloader logic or firmware update recovery mechanisms. You should update this value before triggering a system reset (using ca_os_reset) to ensure the bootloader selects the correct image. Warning: Providing an invalid slot index or an incorrect magic number will cause the bootloader to fail or fall back to a safe state, potentially bricking the device if no valid image is found.

`CA_BOOT_SUPPORTED`

File: `caos/inc/boot_image.h`

Enables or disables the bootloader support features within the caOS firmware.

Valore: `1`

Note:
When set to 1, the system includes the necessary code to handle firmware updates, image verification, and boot slot management. This flag is a prerequisite for using the ca_boot_* API functions. If disabled (0), the bootloader logic is excluded from the build, reducing the binary size but preventing remote or local firmware updates.

Uso:
Set this to 1 when your project requires field-upgradable firmware or dual-bank bootloader support. You must ensure that your memory map is configured to accommodate the bootloader and application slots. If you are developing a simple application that does not require updates, you may set this to 0 to save flash memory.

`CA_BOOT_TRIAL_MS`

File: `caos/inc/boot_image.h`

Defines the duration in milliseconds for the trial period of a new firmware image.

Valore: `60000U`

Note:
This constant determines how long the system waits for a confirmation after a new firmware update is applied. If ca_boot_confirm() is not called within this time, the system assumes the update is faulty and reverts to the previous stable image. The value is in milliseconds; 60000U equals 60 seconds. This is a system-wide configuration and should be consistent with the application's startup time requirements.

Uso:
Increase this value if your application performs complex initialization or network connectivity checks that might delay the call to ca_boot_confirm(). Decrease it if you want the system to revert faster in case of a boot loop or hang. Ensure the value is long enough to allow the application to reach the confirmation point under worst-case conditions.

`CA_CONFIG_HASH_LEN`

File: `caos/inc/caos_info.h`

Defines the fixed length in bytes for the internal task and resource hash identifiers used by the caOS kernel.

Valore: `32u`

Note:
This constant determines the memory footprint of the hash table entries. Increasing this value improves collision resistance for large task sets but consumes more RAM. It must be a power of two or a multiple of the system word size for optimal performance. Typical values range from 16 to 64 depending on the number of registered system objects.

Uso:
Adjust this value if the system reports hash collisions or if you are scaling the application to include a significantly higher number of tasks and semaphores. Do not change this value unless you are re-compiling the entire kernel, as it affects the binary structure of the task control blocks.

CA_DMA2D_AI

File: caos/drivers/inc/dma2d.h

Enables the DMA2D Abstraction Interface (AI) for hardware-accelerated graphics operations.

Valore: 0x01U

Note:
When set to 0x01U, the caOS DMA2D driver uses the abstraction layer to interface with the STM32 hardware. Disabling this (0x00U) will cause ca_dma2d_* functions to return errors or fail to initialize. This flag is a prerequisite for using hardware-accelerated pixel copying, blending, and filling operations.

Uso:
Enable this flag when your project requires high-performance GUI rendering or image processing using the STM32 DMA2D peripheral. If your hardware does not have a DMA2D controller or you are performing software-only rendering, set this to 0x00U to save code space and avoid peripheral initialization errors.

CA_DMA2D_CLUT_CPU

File: caos/drivers/inc/dma2d.h

Flag defining the CPU-based Color Look-Up Table (CLUT) processing mode for the DMA2D peripheral.

Valore: 0x04U

Note:
This constant is used as a bitmask or configuration parameter within the ca_dma2d_init or related configuration functions. When enabled, it instructs the DMA2D driver to handle CLUT color conversion via CPU-assisted routines rather than relying solely on hardware-accelerated DMA2D registers. It is typically used when the hardware DMA2D engine lacks specific support for certain pixel formats or when custom color mapping is required. It does not have direct dependencies on other flags but should be used in conjunction with valid CLUT memory buffers.

Uso:
Change this value only if you are implementing custom graphics drivers or if the standard hardware-accelerated DMA2D operations fail to render specific indexed color formats correctly. Warning: Enabling CPU-based processing will significantly increase CPU load during graphics operations, potentially impacting the real-time performance of other tasks. Use only when hardware-only rendering is insufficient for your specific display requirements.

CA_DMA2D_ERR_ARG

File: caos/drivers/inc/dma2d.h

Error flag indicating an invalid argument was passed to a DMA2D function.

Valore: 0x10U

Note:
This constant is used by the ca_dma2d_errors() function to report that a parameter provided to a DMA2D operation (such as an invalid buffer address, incorrect color format, or out-of-bounds

coordinate) is invalid. It is a bitmask value (0x10U) that can be combined with other error flags. It does not depend on other flags but is triggered by improper usage of the ca_dma2d_* API.

Uso:
Check for this flag when a DMA2D operation fails to return success. If this error occurs, verify that all pointers, dimensions, and color format constants passed to functions like ca_dma2d_copy or ca_dma2d_fill are within valid ranges and properly aligned as required by the STM32 hardware.

`CA_DMA2D_ERR_CAE`

File: `caos/drivers/inc/dma2d.h`

Configuration flag representing a Configuration Access Error (CAE) in the DMA2D peripheral.

Valore: `0x04U`

Note:
This constant is used as a bitmask or error code within the ca_dma2d_errors() function. When the DMA2D hardware detects an invalid configuration (such as incorrect pixel format or invalid memory address alignment), it sets this error flag. It is typically checked after a DMA2D operation fails to determine the root cause. It is a read-only status flag defined by the hardware driver layer.

Uso:
Use this constant when debugging DMA2D operations. If ca_dma2d_errors() returns a value where (result & CA_DMA2D_ERR_CAE) is true, verify your input parameters passed to ca_dma2d_copy() or ca_dma2d_blend(). Ensure that source and destination buffers are correctly aligned and that the pixel format matches the hardware capabilities.

`CA_DMA2D_ERR_CE`

File: `caos/drivers/inc/dma2d.h`

Configuration flag representing a Configuration Error (CE) in the DMA2D peripheral.

Valore: `0x02U`

Note:
This constant is a bitmask value (0x02U) used within the ca_dma2d_errors() function to identify if a configuration error occurred during a DMA2D transfer. It is typically checked alongside other error flags. When this bit is set in the error register, it indicates that the DMA2D hardware was provided with invalid parameters (e.g., unsupported color format or invalid memory address).

Uso:
Use this flag when debugging DMA2D transfer failures. If ca_dma2d_errors() returns a value where (result & CA_DMA2D_ERR_CE) is true, verify your input parameters such as pixel format, buffer alignment, or memory addresses passed to ca_dma2d_copy() or ca_dma2d_blend(). Do not modify this constant value as it is mapped directly to the hardware status register.

`CA_DMA2D_ERR_TE`

File: `caos/drivers/inc/dma2d.h`

Flag representing a Transfer Error (TE) interrupt or status bit for the DMA2D peripheral.

Valore: `0x01U`

Note:
This constant is used to identify or mask the Transfer Error interrupt flag in the DMA2D hardware. When enabled in the interrupt configuration, the system will trigger an error callback if the DMA2D hardware encounters a bus error or configuration issue during a memory transfer. It is typically used in conjunction with ca_dma2d_errors to check the status of the peripheral.

Uso:
Use this flag when configuring DMA2D interrupts or checking error status registers to detect hardware transfer failures. If your graphics operations are failing silently, check if this error bit is set. Do not modify this value as it corresponds to the specific hardware register bit defined in the STM32 reference manual.

`CA_DMA2D_ERR_TMO`

File: `caos/drivers/inc/dma2d.h`

Defines the timeout value for DMA2D error handling operations.

Valore: `0x08U`

Note:
This constant sets the maximum number of cycles or ticks the system waits for the DMA2D peripheral to recover from an error state. If the DMA2D hardware fails to clear its error flags within this threshold, the driver will report a failure. It is typically used in conjunction with ca_dma2d_errors. Increasing this value may be necessary if the system bus is heavily loaded, while decreasing it makes the system more responsive to hardware hangs.

Uso:
Adjust this value if you encounter frequent 'DMA2D timeout' errors during heavy graphical operations or when the system bus is congested. If the value is too low, the system may falsely report hardware errors; if too high, the system may hang for an extended period before detecting a genuine hardware failure.

`CA_DMA2D_HW_TC`

File: `caos/drivers/inc/dma2d.h`

Defines the bitmask for the DMA2D Transfer Complete (TC) interrupt flag.

Valore: `0x100U`

Note:
This constant represents the hardware-specific bit position for the Transfer Complete interrupt in the DMA2D Interrupt Status Register. It is used internally by the ca_dma2d_* driver functions to check or clear the interrupt status. It should not be modified unless the underlying STM32 hardware register mapping changes.

Uso:

This value is used by the caOS DMA2D driver to identify when a hardware graphics operation has finished. You do not need to change this value for standard application development. If you are porting caOS to a new STM32 chip, verify this value against the specific Reference Manual for the DMA2D peripheral.

`CA_DMA2D_OUT_FMTS`

File: `caos/drivers/inc/dma2d.h`

Defines the default output pixel format for the DMA2D (Chrom-ART) peripheral.

Valore: `5U`

Note:
This constant sets the hardware register configuration for the DMA2D output color mode. A value of 5U typically corresponds to ARGB8888 format in STM32 hardware. Changing this affects how the DMA2D engine interprets and writes pixel data to the frame buffer. It must be compatible with the display driver and memory layout used in your project.

Uso:
Change this value only if you are switching to a different color depth or pixel format (e.g., RGB565 or RGB888) for your display output. Ensure the hardware supports the new format before modifying. Incorrect values will result in corrupted graphics, color inversion, or display artifacts.

`CA_DMA2D_RBS`

File: `caos/drivers/inc/dma2d.h`

Configures the DMA2D Request Burst Size (RBS) for memory-to-memory transfers.

Valore: `0x02U`

Note:
This constant defines the number of beats in a burst transfer for the DMA2D controller. A value of 0x02U typically corresponds to a 4-beat burst. Increasing this value can improve throughput for large memory copies by reducing bus arbitration overhead, but it may increase bus latency for other peripherals. It is hardware-dependent and must align with the STM32 DMA2D peripheral specifications.

Uso:
Modify this value only if you encounter performance bottlenecks during heavy graphical operations or memory copies. If the system experiences bus contention or graphical artifacts, verify that the burst size is supported by the specific STM32 chip's DMA2D implementation. Incorrect values may lead to DMA2D transfer errors or system instability.

`CA_ETH_ERR_BUS`

File: `caos/drivers/inc/eth.h`

A bitmask flag indicating that the Ethernet peripheral has encountered a bus-level communication error.

Valore: `(1U ≪ 0)`

Note:

This flag is set in the Ethernet status register when the DMA fails to access the system bus (e.g., AHB bus error). It is typically used within the Ethernet interrupt service routine (ISR) to trigger a driver reset or error recovery sequence. It is a bit-field constant, so it must be used with bitwise operators (e.g., status & CA_ETH_ERR_BUS).

Uso:
Use this flag when implementing custom error handling logic in the Ethernet driver. You should check this flag if the network interface stops transmitting or receiving packets unexpectedly. Do not modify the value itself, as it corresponds to a specific hardware register bit defined by the STM32 Ethernet peripheral architecture.

`CA_ETH_ERR_RBU`

File: `caos/drivers/inc/eth.h`

Error flag indicating that the Ethernet Receive Buffer is unavailable (RBU).

Valore: `(1U « 1)`

Note:
When this bit is set in the status register, it means the DMA has run out of descriptors to store incoming packets. This flag is typically checked within the Ethernet ISR or the driver's polling loop. It depends on the CA_ETH_ENABLE_INTERRUPTS flag being active to trigger an error callback.

Uso:
Use this flag to diagnose packet loss during high network traffic. If this error occurs frequently, increase the number of RX descriptors in the Ethernet configuration or optimize the task processing the incoming data to prevent buffer exhaustion.

`CA_ETH_ERR_RPS`

File: `caos/drivers/inc/eth.h`

A bitmask flag representing a Receive Packet Stall (RPS) error condition in the Ethernet driver.

Valore: `(1U « 3)`

Note:
When enabled, this flag indicates that the Ethernet DMA has stopped receiving packets due to a buffer exhaustion or descriptor ring stall. It is part of the CA_ETH_ERR_MASK and is typically checked within the Ethernet ISR. It depends on the hardware DMA status registers being correctly mapped to the caOS driver layer.

Uso:
Use this flag when debugging network throughput drops or intermittent connection losses. If this bit is frequently set in the error status register, it indicates that the application is not processing incoming packets fast enough, requiring an increase in the RX descriptor count or a higher priority for the Ethernet task.

`CA_ETH_ERR_TPS`

File: `caos/drivers/inc/eth.h`

A bitmask flag representing a Transmit Packet Stall (TPS) error condition in the Ethernet driver.

Valore: `(1U « 2)`

Note:
When this bit is set in the Ethernet error status register, it indicates that the DMA engine has stalled during packet transmission. This flag is part of the CA_ETH_ERR_MASK and is typically checked within the Ethernet ISR. It depends on the hardware DMA state machine being active and the Ethernet peripheral being initialized.

Uso:
Use this flag when debugging network transmission timeouts or 'stuck' Ethernet interfaces. If this error occurs frequently, it usually indicates a buffer descriptor chain issue or a hardware-level DMA hang. Do not modify the bit position unless updating the entire driver's error handling logic to match the hardware register map.

`CA_ETH_SEND_ERR_LINK`

File: `caos/drivers/inc/eth.h`

Error code indicating that an Ethernet packet transmission failed because the network link is currently down.

Valore: `(-102)`

Note:
This constant is returned by the Ethernet driver's send function when the physical link status (PHY) is disconnected. It is a negative integer value (-102) used for error handling in the application layer. It depends on the PHY status register being correctly polled or updated via interrupt.

Uso:
Use this value in your error-checking logic after calling the Ethernet send function. If you receive this code, you should stop attempting to send data and wait for the link-up event before retrying. Do not modify this value as it is a reserved system error code.

`CA_ETH_SEND_ERR_TX`

File: `caos/drivers/inc/eth.h`

Error code returned by the Ethernet driver when a transmission buffer fails to send.

Valore: `(-101)`

Note:
This constant represents a specific negative integer error state (-101) indicating a hardware or DMA failure during the packet transmission process. It is typically checked by the network stack after calling the low-level transmit function. It does not have configurable ranges as it is a fixed return value, but it depends on the underlying HAL_ETH_Transmit status.

Uso:

Use this constant in your application code to handle Ethernet transmission failures gracefully. If you encounter this error frequently, check the Ethernet cable connection, verify that the DMA descriptors are correctly initialized, and ensure that the network buffer pool is not exhausted. Do not modify this value as it is defined by the caOS driver architecture.

`CA_ETH_SEND_OK`

File: `caos/drivers/inc/eth.h`

Defines the return status code indicating a successful Ethernet packet transmission.

Valore: `0`

Note:
This constant is used by the Ethernet driver's transmit function to signal that the buffer was successfully handed off to the DMA controller. It is typically compared against the return value of the 'eth_send' function. It must remain 0 to maintain compatibility with standard C error handling conventions where 0 represents success.

Uso:
Do not change this value unless you are porting the driver to a new hardware abstraction layer that uses a different convention for success codes. Changing this value will break all existing driver logic that checks for successful packet transmission, likely causing the network stack to report false errors.

`CA_EVENT_BIT`

File: `caos/inc/event.h`

Defines a specific bit position within an event group to represent a unique system event.

Valore: `(1U « (n))`

Note:
This macro creates a bitmask where 'n' represents the bit index (0-31). Enabling a specific bit allows a task to wait for or signal a unique event flag. It depends on the event group size defined in the RTOS kernel. Valid values for 'n' are typically 0 to 31 for a 32-bit event register.

Uso:
Use this when you need to signal or synchronize tasks based on specific conditions (e.g., data ready, error occurred). Change 'n' to assign a unique identifier to each event. Warning: Ensure 'n' does not exceed the maximum bit width of the event group, or you will trigger undefined behavior or silent failures in event signaling.

`CA_EVENT_WAIT_ALL`

File: `caos/inc/event.h`

A flag used in event group operations to require all specified bits to be set before a task is unblocked.

Valore: `1`

Note:
When enabled (set to 1), the task will wait for the logical AND of all requested event bits. If disabled (set to 0), the task will unblock if any one of the requested bits is set (logical OR). This

flag is typically passed as an argument to the ca_event_wait() function. It has no dependencies on other system flags but directly dictates the synchronization logic of the event group.

Uso:
Use this flag when your task needs to synchronize with multiple independent conditions simultaneously, such as waiting for both a sensor data ready signal and a timer interrupt. Do not use this if you only need one of several events to trigger the task, as it will cause the task to hang indefinitely if one of the required events never occurs.

`CA_EVENT_WAIT_ANY`

File: `caos/inc/event.h`

A flag used in event synchronization to trigger a task wake-up if any one of the specified events occurs.

Valore: `0`

Note:
When enabled (set to 0), the task will unblock as soon as at least one bit in the event mask is set. This is the logical OR operation for event waiting. It is the default behavior for event synchronization in caOS. It does not require additional memory but changes the scheduler's condition check from a bitwise AND to a bitwise OR.

Uso:
Use this flag when a task needs to respond to multiple independent triggers, such as 'Data Ready' OR 'Error Occurred'. Do not use this if the task requires all specified events to be present before proceeding; for that, use the CA_EVENT_WAIT_ALL flag instead. Setting this incorrectly may cause tasks to wake up prematurely, leading to race conditions if the logic expects a complete set of data.

`CA_FAULT_ASSERT`

File: `caos/inc/scheduler.h`

A global configuration flag that determines whether the system triggers a hard fault or enters an infinite loop when a kernel assertion fails.

Valore: `0x00`

Note:
When set to 1, the system executes a software breakpoint or triggers a hard fault upon an assertion failure, which is useful for debugging. When set to 0, the system enters a silent infinite loop to prevent undefined behavior in production. This flag depends on the CA_DEBUG_MODE macro; if CA_DEBUG_MODE is disabled, this flag is ignored.

Uso:
Set this to 1 during the development and testing phase to catch logic errors immediately via the debugger. Set this to 0 for production firmware to ensure the system remains in a controlled state if an unexpected condition occurs, preventing erratic behavior in the field.

CA_FAULT_CHECK

File: `caos/inc/scheduler.h`

Configures the level of hardware fault detection and stack overflow monitoring performed by the caOS kernel.

Valore: `0x03`

Note:
The value 0x03 acts as a bitmask enabling both stack boundary checking and CPU exception trapping. Disabling this (setting to 0x00) reduces CPU overhead but makes debugging memory corruption or illegal instruction errors significantly harder. It depends on the hardware MPU (Memory Protection Unit) being correctly initialized in the system startup code.

Uso:
Enable this during development and integration testing to catch buffer overflows and invalid pointer dereferences early. You should only consider disabling it in final production builds if you have strictly verified memory safety and require absolute minimum interrupt latency, though it is generally recommended to keep it enabled for system stability.

CA_FAULT_EXEC_EMERGENCY

File: `caos/inc/scheduler.h`

Defines the emergency execution mode flag used by the scheduler during critical system fault recovery.

Valore: `0x02`

Note:
When this flag is set, the scheduler bypasses standard task switching logic to prioritize the execution of emergency recovery routines. It depends on the CA_FAULT_HANDLER_ENABLED flag being active. The value 0x02 is a bitmask; ensure it does not conflict with other scheduler state flags in the bitfield.

Uso:
Change this value only if you are modifying the core scheduler architecture or porting to a new STM32 series with different fault handling requirements. Setting this incorrectly can lead to a system hang or an infinite loop during a fault condition, preventing the watchdog from resetting the device.

CA_FAULT_RESTART_THREAD

File: `caos/inc/scheduler.h`

Determines if the scheduler should attempt to restart a thread after a fault occurs.

Valore: `0x01`

Note:
When enabled (0x01), the kernel will attempt to re-initialize the thread's stack and context upon a fault exception. If disabled, the thread remains in a suspended or terminated state. This flag depends on the system having enough memory to re-allocate the thread control block and stack. Typical values are 0x01 (enabled) or 0x00 (disabled).

Uso:

Enable this flag during development to keep the system running after non-critical thread crashes. Disable it in production if you prefer the system to enter a safe state or trigger a full watchdog reset upon encountering a fault, as restarting a corrupted thread may lead to unpredictable system behavior.

CA_FMAC_FIR_MAX

File: caos/drivers/inc/fmac.h

Defines the maximum number of taps (coefficients) supported by the FMAC FIR filter engine.

Valore: 127U

Note:
This constant sets the upper limit for the FIR filter length in the FMAC driver. Increasing this value allows for more complex filtering but consumes more memory for coefficient storage. The value 127 is the hardware-imposed limit for the STM32 FMAC peripheral. Ensure your filter design does not exceed this count, or the driver will fail to initialize the filter parameters.

Uso:
Change this value only if you need to reduce memory footprint and are certain your application will never require a filter with more than the new, lower limit. Do not increase it beyond 127, as it will exceed the hardware capability of the FMAC peripheral. If your filter design requires more than 127 taps, you must implement a multi-stage filtering approach or use a different processing method.

CA_FMAC_IIR_MAX

File: caos/drivers/inc/fmac.h

Defines the maximum number of coefficients supported by the FMAC (Filter Math Accelerator) IIR filter implementation.

Valore: 64U

Note:
This constant sets the upper limit for the IIR filter order or coefficient array size. Increasing this value consumes more static memory (RAM) for the filter state buffers. It must be large enough to accommodate the highest order filter used in your application. Typical values are powers of 2, such as 64, 128, or 256, depending on the available heap and the complexity of the signal processing tasks.

Uso:
Change this value if you encounter errors when initializing complex IIR filters or if you need to optimize memory usage by reducing it to the minimum required for your specific filter design. If you attempt to initialize a filter with more coefficients than this constant allows, the ca_fmac_init function will likely fail or return an error code.

CA_FMAC_OVFL

File: caos/drivers/inc/fmac.h

Flag representing the FMAC (Filter Math Accelerator) overflow error condition.

Valore: 0x02U

Note:
This constant is used as a bitmask within the ca_fmac_flags() function to check if the FMAC hardware has encountered an arithmetic overflow during calculation. When this bit is set in the status register, it indicates that the result of the filter operation exceeded the representable range of the output format. It is typically used in conjunction with other status flags to validate the integrity of signal processing data.

Uso:
Use this flag when polling or checking the FMAC status after a computation to ensure the output data is valid. If this flag is detected, the current filter output should be considered unreliable. You should check this value if your application performs high-gain filtering or processes signals with high dynamic range that might cause saturation.

`CA_FMAC_SAT`

File: `caos/drivers/inc/fmac.h`

Enables hardware saturation logic for the FMAC (Filter Math Accelerator) peripheral.

Valore: `0x01U`

Note:
When set to 0x01U, the FMAC hardware automatically clamps output results to the maximum or minimum representable values if an overflow occurs during calculation. If disabled (0x00U), the result will wrap around, which can lead to significant signal distortion in DSP applications. This flag is typically used in conjunction with ca_fmac_init to configure the peripheral's operational mode.

Uso:
Enable this flag when performing filtering operations (like FIR or IIR) where numerical stability is critical and you want to prevent wrap-around artifacts. Disable it only if your specific algorithm requires modular arithmetic or if you are manually handling overflow protection in software to save clock cycles.

`CA_FMAC_UNFL`

File: `caos/drivers/inc/fmac.h`

Flag to enable underflow detection in the FMAC (Filter Math Accelerator) peripheral.

Valore: `0x04U`

Note:
When enabled (0x04U), the FMAC hardware will trigger an interrupt or error state if a calculation result underflows the representable range. This is typically used in conjunction with other FMAC flags to configure the peripheral's behavior during signal processing. It depends on the hardware support for FMAC error reporting on the specific STM32 series being used.

Uso:
Use this flag when performing high-precision digital filtering where you need to detect if signal values become too small to be represented accurately by the fixed-point format. If you notice unexpected signal clipping or loss of precision in your filter output, enable this flag to debug potential underflow conditions. Warning: enabling this may cause the FMAC to stop processing or trigger an error handler if an underflow occurs, so ensure your application has a proper error recovery strategy using ca_fmac_init or similar.

CA_ICMP_PAYLOAD

File: caos/net/inc/net_proto.h

A pointer offset macro used to locate the start of the data payload within an ICMP echo packet.

Valore: ((u8 *)(icmp) + sizeof(ca_icmp_echo_t))

Note:
This constant calculates the memory address immediately following the ICMP header structure (ca_icmp_echo_t). It is used by the network stack to read or write the payload section of a ping request or reply. It depends on the structure alignment of ca_icmp_echo_t; if the header size changes, this macro must remain synchronized to avoid memory corruption or data misalignment.

Uso:
Use this macro when you need to access the raw data buffer of an ICMP packet for inspection or modification. Do not manually calculate this offset using hardcoded integers, as it will break if the header structure is modified. Ensure that the packet buffer is large enough to hold the payload before accessing this address to prevent buffer overflows.

CA_IP4_IHL

File: caos/net/inc/net_proto.h

Calculates the length of the IPv4 header in bytes based on the IHL field.

Valore: (((ip4)->ver_ihl & 0x0Fu) « 2)

Note:
The IHL (Internet Header Length) field represents the number of 32-bit words in the header. Multiplying this value by 4 (via the left shift by 2) converts the count into the total byte size. This value is dynamic and depends on the presence of IP options. It must be used only when the IP header is valid.

Uso:
Use this macro when parsing incoming network packets to determine where the payload begins relative to the start of the IP header. Do not modify the macro definition itself; incorrect usage will lead to buffer overflows or memory corruption if the calculated offset points outside the packet buffer.

CA_IP4_PAYLOAD

File: caos/net/inc/net_proto.h

A macro that calculates the memory address where the actual data payload begins within an IPv4 packet.

Valore: ((u8 *)(ip4) + CA_IP4_IHL(ip4))

Note:
This macro adds the length of the IPv4 header (IHL) to the base pointer of the IP packet. It is essential for accessing the transport layer data (like TCP or UDP segments). It depends on the CA_IP4_IHL macro, which parses the header length field. The result is a pointer to the first byte of the payload.

Uso:
Use this whenever you need to extract or process the data carried by an IP packet. Do not modify this macro unless you are porting the stack to a non-standard network architecture. Incorrect usage will lead to memory access violations or data corruption if the pointer calculation points outside the valid packet buffer.

`CA_JPEG_ERR_ARG`

File: `caos/drivers/inc/jpeg.h`

Error code indicating an invalid argument was passed to a JPEG driver function.

Valore: `0x01U`

Note:
This constant is returned by functions in the ca_jpeg module when input parameters (such as pointers, buffer sizes, or configuration structures) fail validation checks. It is a specific error flag used within the ca_jpeg_errors enumeration. It does not depend on other flags but is part of the standard error handling flow for the JPEG hardware peripheral.

Uso:
Check for this value when calling ca_jpeg_decode or ca_jpeg_encode. If a function returns this error, verify that your input buffers are correctly aligned, pointers are not null, and the image dimensions provided to ca_jpeg_geometry are within hardware limits. Example: if (ca_jpeg_decode(data, size) == CA_JPEG_ERR_ARG) { /* handle invalid input */ }.

`CA_JPEG_ERR_HDR`

File: `caos/drivers/inc/jpeg.h`

Error flag indicating a corrupted or invalid JPEG header detected during decoding.

Valore: `0x08U`

Note:
This constant is used as a bitmask within the ca_jpeg_errors() function. When the JPEG decoder encounters a malformed header (e.g., missing SOI marker or invalid quantization tables), it sets this bit in the error status register. It is a read-only status flag and does not require configuration; it is strictly for diagnostic purposes when ca_jpeg_decode() returns a non-zero value.

Uso:
Check this flag when ca_jpeg_decode() fails to determine if the issue is due to a bad input file rather than a hardware or memory issue. If this flag is set, verify the integrity of the JPEG source data buffer before passing it to the decoder again. Do not attempt to modify this value.

`CA_JPEG_ERR_OVF`

File: `caos/drivers/inc/jpeg.h`

JPEG hardware decoder overflow error flag.

Valore: `0x04U`

Note:

This constant represents a bitmask (0x04U) indicating that the JPEG hardware peripheral has encountered an overflow condition during data processing. It is typically used within the ca_jpeg_errors() function to check the status of the hardware decoder. When this flag is set, it means the input buffer or the internal FIFO has been overwhelmed, usually due to data arriving faster than the decoder can process it or an incorrectly formatted JPEG stream.

Uso:
Check this flag when ca_jpeg_errors() returns a non-zero value to determine if the failure was caused by an overflow. If this error occurs, verify the input data stream integrity and ensure the DMA or interrupt service routine feeding the JPEG peripheral is not being starved by higher-priority tasks. Do not attempt to continue decoding if this flag is raised; reset the JPEG peripheral using ca_jpeg_init() before attempting a new operation.

`CA_JPEG_ERR_TMO`

File: `caos/drivers/inc/jpeg.h`

Defines the timeout error flag for JPEG hardware operations.

Valore: `0x02U`

Note:
This constant represents a specific bitmask or error code returned by the JPEG driver when a hardware operation exceeds the expected time limit. It is typically used in conjunction with ca_jpeg_errors to identify if a failure was caused by a timeout rather than a data corruption or configuration issue. The value 0x02U is a bit-field constant.

Uso:
Use this value when checking the return status of ca_jpeg_decode or ca_jpeg_encode. If the driver returns an error, perform a bitwise AND with CA_JPEG_ERR_TMO to determine if the hardware hung. If this error occurs frequently, verify the clock configuration of the JPEG peripheral or ensure the input data stream is not stalling the DMA transfer.

`CA_JPEG_HW_EOC`

File: `caos/drivers/inc/jpeg.h`

Flag representing the End of Conversion (EOC) interrupt bit for the hardware JPEG peripheral.

Valore: `0x400U`

Note:
This constant is a bitmask (0x400U) used to identify or clear the hardware interrupt status register for the JPEG codec. It is typically used within the ca_jpeg_* driver functions to verify if a hardware-accelerated encoding or decoding operation has finished. It depends on the underlying STM32 JPEG peripheral register map.

Uso:
Do not modify this value unless you are porting the driver to a different STM32 series with a different register layout. It is used internally by the ca_jpeg driver to handle hardware synchronization. If you are implementing a custom interrupt handler or polling mechanism for JPEG operations, use this flag to check the status register via the hardware abstraction layer.

`CA_JPEG_HW_HDR`

File: `caos/drivers/inc/jpeg.h`

Enables hardware-accelerated High Dynamic Range (HDR) processing for JPEG operations.

Valore: `0x800U`

Note:
When enabled (0x800U), the ca_jpeg driver utilizes dedicated STM32 hardware peripherals to perform HDR-related color space transformations or tone mapping during JPEG encoding/decoding. This flag is typically used in conjunction with other JPEG configuration bits. If the specific STM32 hardware variant does not support hardware HDR, enabling this flag may result in undefined behavior or driver initialization errors.

Uso:
Enable this flag only when the application requires high-performance HDR image processing and the underlying hardware supports it. If you encounter image artifacts or driver crashes during JPEG operations, verify if your hardware supports this feature before enabling. For standard JPEG tasks without HDR requirements, keep this flag disabled to save system resources and ensure compatibility.

`CA_JPEG_HW_IN_FREE`

File: `caos/drivers/inc/jpeg.h`

Flag indicating that the JPEG hardware peripheral is available and initialized in the system.

Valore: `0x100U`

Note:
When enabled (0x100U), the ca_jpeg_* API functions will attempt to utilize the STM32 hardware JPEG codec. If disabled or not defined, the system may fall back to software-based processing or return an error if hardware acceleration is required. This constant is typically used in the board support package (BSP) configuration to define hardware capabilities.

Uso:
Change this value only if you are porting the code to a different STM32 variant that lacks a hardware JPEG peripheral. If you are working on a board that does not have a JPEG hardware block, ensure this flag is not set to avoid attempting to access non-existent memory-mapped registers, which would trigger a hard fault.

`CA_JPEG_HW_OUT_DATA`

File: `caos/drivers/inc/jpeg.h`

Defines the hardware output data register offset for the JPEG peripheral.

Valore: `0x200U`

Note:
This constant represents the memory-mapped offset used by the JPEG hardware accelerator to output processed pixel data. It is typically used internally by the ca_jpeg_* API functions. Changing this value will break communication with the STM32 JPEG hardware block, leading to decoding or encoding failures. It is a fixed hardware-dependent constant and should not be modified by the application layer.

Uso:
Do not change this value. It is used by the driver to correctly interface with the STM32 JPEG peripheral registers. If you encounter JPEG processing errors, verify that the hardware initialization via ca_jpeg_init was successful rather than modifying this constant.

`CA_L2_PAYLOAD`

File: `caos/net/inc/net_proto.h`

Calculates the memory address where the actual data payload begins within a Layer 2 network frame.

Valore: `((u8 *)(l2) + sizeof(ca_l2_frame_t))`

Note:
This macro adds the size of the L2 header structure to the base address of the frame buffer. It is a pointer arithmetic operation. It depends on the definition of 'ca_l2_frame_t' and must be used only after the frame header has been correctly initialized. The resulting address must be aligned according to the CPU architecture requirements to avoid bus faults.

Uso:
Use this constant whenever you need to access or copy the data portion of a received packet. Change this only if you modify the structure of the L2 header. Warning: Incorrect usage will lead to memory corruption or reading garbage data, as it will point to the wrong offset in the packet buffer.

`CA_L2_VLAN_PAYLOAD`

File: `caos/net/inc/net_proto.h`

Calculates the memory offset to the start of the payload data within an 802.1Q VLAN-tagged Ethernet frame.

Valore: `((u8 *)(l2v) + sizeof(ca_l2_vlan_frame_t))`

Note:
This macro adds the size of the VLAN header structure to the base pointer of the Layer 2 frame. It is strictly dependent on the ca_l2_vlan_frame_t structure definition. If the VLAN header size changes or padding is added by the compiler, this macro must be updated to prevent memory misalignment or buffer overflows.

Uso:
Use this when parsing incoming network packets to correctly locate the encapsulated IP or ARP data. Do not modify this value manually unless you are changing the underlying network frame structure; incorrect offsets will lead to corrupted packet processing or hard faults when accessing the payload buffer.

`CA_LED_COUNT`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`

File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the total number of physical status LEDs available on the specific STM32 hardware target.

Valori per MCU:

MCU	Valore
F103	1U
F407	1U
F429	3U
F446	3U
F746	3U
H563	3U
H747	3U
H753	3U

Note:
This constant determines the size of the internal LED control array. Enabling this allows the caOS HAL to manage multiple status indicators (e.g., system heartbeat, error, and activity). It must match the hardware schematic of your specific board. Values range from 1 to 3 depending on the MCU series; setting a value higher than the physical hardware will result in out-of-bounds memory access during LED initialization.

Uso:
Change this value only when porting caOS to a new custom PCB or a different STM32 development board. If you are using a standard supported board, keep the default value provided in the board configuration file. Incorrect values will cause the system to hang during the boot sequence or trigger a HardFault when attempting to toggle non-existent GPIO pins.

`CA_LED_TABLE`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the hardware mapping table for system status LEDs across different STM32 MCU architectures.

Valori per MCU:

MCU	Valore
F103	\
F407	\
F429	\
F446	\
F746	\
H563	\
H747	\
H753	\

Note:
This constant acts as a lookup table or pointer to the GPIO port and pin definitions for the board's diagnostic LEDs. Enabling or modifying this allows the RTOS to signal system states (like heartbeat or error codes) via physical LEDs. It is hardware-dependent; selecting the wrong table for your specific MCU (e.g., F407 vs H747) will result in incorrect GPIO toggling or potential hardware faults if pins are misconfigured.

Uso:
Change this value only when porting the caOS RTOS to a new hardware target or when changing the physical LED wiring on a custom PCB. Ensure the selected table matches the specific MCU variant defined in your project settings. Incorrect values will lead to silent failures in system diagnostics, making it difficult to debug RTOS kernel panics or initialization errors.

`CA_MEMMAP_COUNT`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the total number of memory regions or memory banks managed by the caOS memory protection unit (MPU) or memory map manager.

Valori per MCU:

MCU	Valore
F103	2U
F407	3U
F429	3U
F446	3U
F746	4U
H563	2U
H747	4U
H753	5U

Note:
This constant dictates how many memory segments the RTOS kernel tracks for access control and allocation. Increasing this value allows for more granular memory partitioning but consumes more RAM for the internal management structures. It must match the hardware capabilities of the specific STM32 series (e.g., 2 for F103, 5 for H753). Setting this value incorrectly can lead to memory access faults or kernel panics during initialization.

Uso:
Change this value only when porting caOS to a new STM32 microcontroller family or when reconfiguring the memory layout of the current MCU. Ensure the value matches the specific hardware datasheet requirements for the target chip. Do not arbitrarily increase this value, as it directly impacts the kernel's memory footprint and stack usage.

`CA_MEMMAP_MAX`

File: `caos/inc/memory.h`

Defines the maximum number of memory regions or segments that the caOS memory manager can track simultaneously.

Valore: `16U`

Note:
This constant sets the size of the internal static array used for memory mapping. Increasing this value allows for more granular memory protection or segment definitions but directly increases the static RAM footprint of the kernel. It must be a positive integer, typically ranging from 8 to 32 depending on the complexity of the application's memory layout.

Uso:
Increase this value if the system fails to initialize or reports a memory mapping error when adding new peripheral memory regions or complex task stacks. Decrease it if you need to optimize RAM usage and your application only requires a few distinct memory segments.

`CA_MEMMAP_TABLE`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the memory layout and peripheral base address mapping for the specific STM32 target MCU.

Valori per MCU:

MCU	Valore
`F103`	`\`
`F407`	`\`
`F429`	`\`
`F446`	`\`
`F746`	`\`
`H563`	`\`
`H747`	`\`
`H753`	`\`

Note:
This constant acts as a pointer to the hardware-specific memory map header file. Enabling or selecting a specific MCU variant ensures that the RTOS correctly maps registers, SRAM, and

Flash addresses. It is a mandatory dependency for the HAL and kernel memory management. Valid values are restricted to the supported MCU series (F103, F407, F429, F446, F746, H563, H747, H753).

Uso:
Change this value only when porting the project to a different STM32 hardware target. Setting an incorrect value will lead to immediate hard faults, memory access violations, or peripheral initialization failures. Ensure the selected value matches the physical silicon on your development board exactly.

`CA_MSG_HEADER_SIZE`

File: `caos/inc/message.h`

Defines the number of bytes reserved for the internal header in every caOS message structure.

Valore: `2`

Note:
This value determines the memory offset where the actual message payload begins. Increasing this value consumes more RAM per message buffer. It must be consistent across all compiled modules to prevent memory corruption or misaligned data access. Typical values are small integers representing the size of internal metadata like message IDs or priority tags.

Uso:
Change this value only if you are modifying the core caOS message handling logic or adding new metadata fields to the message header. Setting this value incorrectly will cause the system to read message data from the wrong memory address, leading to unpredictable behavior or hard faults.

`CA_NOTIFY_ACTION_CLEAR_BITS`

File: `caos/inc/notify.h`

Defines the notification action to clear specific bits in the task's notification register upon receipt.

Valore: `2`

Note:
When this flag is used, the bits specified in the notification value are cleared in the target task's internal state after the notification is processed. This is typically used in conjunction with bitwise operations to manage event flags. It is a mutually exclusive option with CA_NOTIFY_ACTION_SET_BITS.

Uso:
Use this flag when you need to implement a 'consume-on-read' mechanism for event flags. It is ideal for clearing specific event triggers once the task has finished handling them. Warning: If you clear bits that other parts of your code are still waiting on, you may cause race conditions or missed events.

`CA_NOTIFY_ACTION_INCREMENT`

File: `caos/inc/notify.h`

Defines the notification action type where the internal counter of a task notification is incremented.

Valore: `4`

Note:
When this flag is used, the target task's notification value is increased by one instead of being overwritten. This is typically used for counting events or signals. It depends on the task notification system being enabled in the kernel configuration. Valid only when passed as an action parameter to the notify API functions.

Uso:
Use this when you need to track the number of occurrences of an event (e.g., counting incoming data packets) rather than just signaling that an event occurred. Do not use this if you need to pass specific bitmasks or data values, as those require the 'overwrite' or 'set bits' actions instead.

`CA_NOTIFY_ACTION_NONE`

File: `caos/inc/notify.h`

A sentinel value indicating that no specific action or callback should be triggered upon a notification event.

Valore: `0`

Note:
When set to this value, the notification system performs no operation, effectively acting as a 'no-op'. It is the default state for notification structures that are initialized but not yet assigned a specific handler. It has no dependencies on other flags and is strictly a constant representing a null-action state.

Uso:
Use this value when initializing a notification structure where you do not want any function to execute or signal to be sent when the event occurs. It is useful for placeholders or disabling specific notification channels without removing the structure from the system. Setting this incorrectly may lead to silent failures where an event occurs but the system appears unresponsive because no action was defined.

`CA_NOTIFY_ACTION_OVERWRITE`

File: `caos/inc/notify.h`

Defines the behavior where a new notification overwrites an existing, unread notification in the queue.

Valore: `3`

Note:
When enabled, the system discards the oldest pending notification if the queue is full, replacing it with the incoming one. This flag is typically used in conjunction with notification handling macros. It requires the notification system to be initialized and is mutually exclusive with blocking notification modes.

Uso:

Use this when you only care about the most recent state or data update and want to prevent the system from stalling due to a full notification buffer. Avoid using this if every notification is critical and must be processed sequentially, as enabling this will lead to data loss.

`CA_NOTIFY_ACTION_SET_BITS`

File: `caos/inc/notify.h`

A notification mode flag that performs a bitwise OR operation on the target task's notification value.

Valore: `1`

Note:
When enabled, the notification value is updated using 'current_value | new_value'. This allows multiple events to be signaled simultaneously without overwriting previous bits. It requires the task to be in a state capable of receiving notifications and is typically used alongside CA_NOTIFY_ACTION_OVERWRITE.

Uso:
Use this when you need to signal multiple independent events to a single task (e.g., flags for UART data, timer expiry, and button press). Avoid using this if you need to pass a specific counter or data value, as bitwise OR will corrupt the data; use CA_NOTIFY_ACTION_OVERWRITE for data passing instead.

`CA_NOTIFY_ACTION_SET_IF_EMPTY`

File: `caos/inc/notify.h`

Flag to set notification value only if no pending value exists

Valore: `5 /**< Write value only if none is pending (value 0),`

Note:
When enabled (value 5), the notification system will only write a new value to the notification structure if there is currently no pending value (indicated by value 0). If a value is already pending, the new value will be ignored. This prevents overwriting important pending notifications. The flag depends on proper initialization of notification structures and requires the notification system to be properly configured. Valid range is 0 (disabled) to 5 (enabled with specific behavior).

Uso:
Enable this flag when you want to prevent notification value overwrites in critical applications where pending notifications must not be lost. Use only when the notification system is properly initialized and when you need to ensure that new values don't overwrite existing pending ones. Disable if you want to allow immediate value updates regardless of pending state. Warning: Setting this flag without proper notification structure initialization may cause unexpected behavior or missed notifications.

`CA_NO_WAIT_TIME`

File: `caos/inc/common.h`

A configuration constant that disables wait time functionality in the caOS RTOS kernel

Valore: `0U`

Note:
When CA_NO_WAIT_TIME is set to 0U (default), the RTOS kernel will not enforce wait time constraints for tasks. This flag typically depends on other timing-related configuration flags like CA_ENABLE_TIMERS. Setting this to 0U removes all wait time limitations, which may cause tasks to block indefinitely. Valid range is typically 0U (disabled) or 1U (enabled), though 0U is the standard default value. When enabled, it may affect task scheduling and system responsiveness.

Uso:
Change this value to 1U only when you need to enable wait time functionality for specific task management requirements. Setting it to 0U (default) is recommended for most applications as it provides maximum flexibility in task scheduling. Warning: Enabling this flag without proper timer configuration may cause system instability or tasks that never complete execution. This flag should be used carefully in real-time applications where deterministic behavior is required.

`CA_PI_MAX_CHAIN`

File: `caos/inc/sync.h`

Defines the maximum number of nested priority inheritance locks allowed for a single task.

Valore: `4U`

Note:
This constant sets the depth of the internal stack used to track priority inheritance chains. Increasing this value consumes more RAM per task control block. It must be at least 1, but typical values range from 2 to 8 depending on the complexity of resource nesting in the application. If a task attempts to acquire more locks than this limit, the system may trigger a kernel panic or fail to grant the mutex.

Uso:
Increase this value if your application architecture involves tasks that hold multiple mutexes simultaneously in a nested fashion (e.g., Task A locks Mutex 1, then Mutex 2, then Mutex 3). If you encounter system instability or assertion failures during complex resource contention, verify if the nesting depth exceeds this constant. Keep it as low as possible to conserve memory.

`CA_PWR_WAKE_LPTIM`

File: `caos/drivers/inc/pwr.h`

Enables the Low Power Timer (LPTIM) as a valid wake-up source for the system from low-power sleep modes.

Valore: `(1U << 2)`

Note:
When enabled, the LPTIM peripheral is configured to trigger an interrupt that exits the CPU from Stop or Standby modes. This flag must be included in the wake-up mask passed to the power management API. It depends on the LPTIM peripheral clock being active during sleep, typically requiring the LSI or LSE clock source to be enabled.

Uso:

Enable this flag when your application requires periodic wake-ups or time-based events while the system is in a low-power state. Do not enable this if the LPTIM is not initialized, as it may cause the system to fail to wake up or trigger spurious interrupts.

CA_PWR_WAKE_LPUART

File: `caos/drivers/inc/pwr.h`

Enables the LPUART peripheral as a valid wake-up source for the system from low-power sleep modes.

Valore: `(1U « 3)`

Note:
When enabled, the LPUART hardware is configured to trigger an interrupt that wakes the CPU from Stop or Standby modes upon receiving data. This flag must be used in conjunction with the system power management driver. If disabled, the LPUART will remain inactive during sleep, preventing serial communication from waking the device. The value is a bitmask intended for use with the CA_PWR_EnableWakeupSource() function.

Uso:
Enable this flag when your application requires the device to remain in a low-power state while waiting for incoming serial commands or data. Ensure the LPUART clock is configured to remain active during sleep in the RCC settings, otherwise, the wake-up signal will not be detected. Do not enable this if the LPUART is not physically connected to an external device, as noise on the RX line could cause unintended wake-ups.

CA_PWR_WAKE_PIN

File: `caos/drivers/inc/pwr.h`

Defines the specific GPIO pin index used to trigger a system wake-up event from low-power sleep modes.

Valore: `(1U « 1)`

Note:
This constant represents a bitmask (1U « 1), targeting Pin 1 of the designated wake-up port. Enabling this flag allows the hardware to transition from standby or stop mode to active mode upon a signal change on this pin. It depends on the CA_PWR_WAKE_PORT configuration being correctly initialized. Valid values are bit-shifted integers corresponding to valid GPIO pins (0-15).

Uso:
Change this value when the hardware design requires a different physical pin to wake the MCU from sleep. Use this to solve issues where the system fails to resume operation after entering low-power states. Warning: Ensure the selected pin is physically connected to the wake-up source; using an incorrect pin will result in the system remaining permanently stuck in sleep mode.

CA_PWR_WAKE_RTC

File: `caos/drivers/inc/pwr.h`

Enables the Real-Time Clock (RTC) alarm as a valid wake-up source for the system from low-power sleep modes.

Valore: `(1U « 0)`

Note:
When enabled, the RTC peripheral is configured to trigger an interrupt that exits the CPU from sleep or stop modes. This flag must be used in conjunction with the system's power management API. If disabled, the RTC will continue to run but will not be capable of waking the processor, potentially causing the system to remain stuck in a low-power state indefinitely if no other wake-up sources are active.

Uso:
Enable this flag when your application requires periodic tasks or scheduled wake-ups based on time (e.g., waking up every hour to send sensor data). Ensure the RTC clock source (LSE or LSI) is correctly initialized before enabling this flag, otherwise, the system may fail to wake up as expected.

`CA_QSPI_DEV_NOR`

File: `caos/drivers/inc/qspi.h`

A configuration flag that enables or disables support for NOR-type flash memory devices on the QSPI peripheral.

Valore: `0U`

Note:
When set to 1U, the driver initializes the specific command sets and timing parameters required for NOR flash chips. When set to 0U, this support is excluded from the build to save code space. This flag depends on the QSPI peripheral being enabled in the system configuration. Valid values are 0U (disabled) or 1U (enabled).

Uso:
Change this value to 1U only if your hardware design includes a NOR flash memory connected to the QSPI bus. If you are using a different type of memory or no QSPI device at all, keep this at 0U to prevent compilation errors or unnecessary memory usage. Setting this to 1U without a physical NOR flash chip present may cause the driver initialization to hang or return errors.

`CA_QSPI_DEV_RAM`

File: `caos/drivers/inc/qspi.h`

Enables or disables the use of internal RAM as a buffer for QSPI flash operations.

Valore: `1U`

Note:
When set to 1U, the driver allocates a dedicated memory buffer in internal SRAM for QSPI data transfers. Disabling this (0U) forces the driver to use direct memory-mapped access or external buffers, which may increase latency. This flag depends on having sufficient free SRAM; if enabled, ensure the linker script provides enough heap or static memory to accommodate the buffer size.

Uso:

Enable this when you need to improve read/write performance for QSPI flash operations by reducing bus contention. Change this to 0U if your application is running low on internal SRAM or if you are using a custom DMA implementation that manages its own memory buffers. Incorrectly enabling this on memory-constrained devices may lead to stack overflows or heap exhaustion.

`CA_QSPI_DEV_RAW`

File: `caos/drivers/inc/qspi.h`

Defines the operating mode of the QSPI peripheral to use raw memory-mapped access instead of a file system or abstraction layer.

Valore: `2U`

Note:
When set to 2U, the QSPI driver bypasses high-level storage drivers and exposes the flash memory as a raw byte-addressable array. This flag is mutually exclusive with CA_QSPI_DEV_FS. Valid values are typically 0U (disabled), 1U (buffered), and 2U (raw).

Uso:
Change this to 2U when you need direct, low-latency access to the flash memory for custom data structures or bootloader operations. Warning: Using raw mode disables built-in wear leveling and file system safety features; ensure your application handles data integrity manually.

`CA_QSPI_MMAP_BASE`

File: `caos/drivers/inc/qspi.h`

Defines the starting memory address where the external QSPI flash is mapped into the STM32 memory space.

Valore: `0x90000000UL`

Note:
This constant sets the base address for memory-mapped mode (XIP). Changing this value must strictly match the memory map defined in the STM32 reference manual for the specific QSPI peripheral instance. It is typically set to 0x90000000 for the first QSPI bank on most STM32 series. Incorrect values will result in hard faults or data corruption when attempting to read from flash memory.

Uso:
Change this value only if you are porting the driver to a different STM32 microcontroller or if the hardware design uses a different memory bank mapping. Ensure that the linker script (.ld file) is updated to reflect this address if you intend to execute code or store constants directly from the QSPI flash.

`CA_QSPI_SSHIFT_AUTO`

File: `caos/drivers/inc/qspi.h`

Enables or disables the automatic shifting of data samples for the Quad-SPI interface.

Valore: `0U`

Note:

When set to 1, the hardware automatically adjusts the sampling clock phase to compensate for signal propagation delays. When set to 0, the sampling phase is fixed. This flag depends on the specific QSPI peripheral clock frequency and PCB trace length. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this if you experience data corruption or CRC errors during high-speed QSPI read operations. Disable it if your hardware design uses a custom clock-delay circuit or if the peripheral is running at low frequencies where timing margins are naturally sufficient. Incorrect configuration may lead to intermittent read failures or complete communication loss.

`CA_QSPI_SSHIFT_AUTO_HZ`

File: `caos/drivers/inc/qspi.h`

Defines the frequency threshold in Hz at which the QSPI driver automatically enables data sampling shift.

Valore: `40000000U`

Note:
When the QSPI clock frequency exceeds this value, the driver enables the internal delay line to compensate for signal propagation delays. If set too low, the system may experience data corruption at high speeds; if set too high, the system may fail to sample data correctly at lower speeds. The default value is 40MHz, which is standard for most QSPI flash memories on STM32 platforms.

Uso:
Adjust this value if you are using a specific QSPI flash chip that requires a different timing margin or if you are operating the QSPI bus at non-standard frequencies. Ensure this value is lower than the maximum clock frequency supported by your external flash memory to prevent read errors.

`CA_QSPI_SSHIFT_OFF`

File: `caos/drivers/inc/qspi.h`

Defines the clock phase shift offset for the Quad-SPI (QSPI) peripheral interface.

Valore: `2U`

Note:
This constant sets the internal delay cycles for the QSPI clock signal relative to the data sampling edge. Increasing this value shifts the clock phase forward, which is critical for maintaining signal integrity at high clock frequencies. It depends on the hardware trace length and the specific flash memory chip's timing requirements. Valid range is typically 0U to 3U, depending on the STM32 hardware revision.

Uso:
Adjust this value if you encounter data corruption or CRC errors during high-speed QSPI read operations. If the system fails to read from external flash reliably, incrementing this value can compensate for propagation delays on the PCB. Warning: setting an incorrect value will cause communication failure or intermittent data bit-flips; always verify with an oscilloscope or logic analyzer when tuning.

CA_QSPI_SSHIFT_ON

File: caos/drivers/inc/qspi.h

Enables the data sampling shift feature for the Quad-SPI peripheral to improve signal integrity.

Valore: 1U

Note:
When set to 1U, the QSPI controller adds a half-cycle delay to the data sampling clock. This is critical for high-frequency QSPI operations where signal propagation delay might cause data to be sampled incorrectly. It depends on the hardware layout and the specific flash memory chip's timing requirements. Valid values are 0U (disabled) or 1U (enabled).

Uso:
Enable this flag if you encounter data corruption or CRC errors during QSPI read operations at high clock speeds. If the system fails to communicate with the external flash after enabling this, verify if your specific hardware design requires the shift or if the clock frequency is too high for the current trace length.

CA_RTC_ALARM_A

File: caos/drivers/inc/rtc.h

Enables the RTC Alarm A interrupt functionality within the caOS driver layer.

Valore: 1u

Note:
When set to 1u, the system initializes and enables the hardware interrupt for Alarm A. If set to 0u, the alarm hardware is ignored, and any associated callback functions will never trigger. This flag depends on the RTC peripheral clock being enabled in the system configuration.

Uso:
Set this to 1u when your application needs to trigger periodic tasks or wake the MCU from low-power modes at a specific time. Disable it (0u) to save code space if your project does not utilize RTC alarms, or to prevent interrupt conflicts if you are manually managing the RTC registers.

CA_RTC_ALARM_B

File: caos/drivers/inc/rtc.h

Defines the hardware alarm channel index used for the RTC alarm interrupt.

Valore: 2u

Note:
This constant specifies which of the available RTC alarm registers (e.g., Alarm A or Alarm B) the system driver will utilize. Setting this to 2u typically maps to Alarm B on STM32 hardware. It must be consistent with the hardware peripheral configuration and should not conflict with other drivers using the same alarm channel. Valid values are typically 1u or 2u depending on the specific STM32 series.

Uso:

Change this value if the system design requires a specific RTC alarm channel for task scheduling or periodic wake-ups. Use this when Alarm A is already reserved by another system component or peripheral. Incorrect values will result in the RTC interrupt failing to trigger, causing the RTOS to miss scheduled events or fail to wake from low-power modes.

`CA_SAFEGUARD`

File: `caos/inc/safeguard.h`

A macro-based dispatcher that validates the number of arguments passed to system-critical RTOS functions.

Valore: `_SAFEGUARD_DISPATCH_(_SAFEGUARD_NARG(__VA_ARGS__))(__VA_ARGS__)`

Note:
This constant acts as a compile-time safety layer. When enabled, it ensures that the correct number of parameters is provided to kernel primitives. If the argument count is mismatched, the compiler will throw an error, preventing undefined behavior or stack corruption. It has no runtime overhead as it is resolved during the pre-processing stage.

Uso:
You should keep this enabled during development and debugging to catch API misuse early. It is typically disabled only in extreme memory-constrained production environments where every byte of pre-processed code size matters, though this is rarely recommended. Do not attempt to redefine this macro unless you are modifying the core kernel dispatch logic.

`CA_SAFE_FAIL`

File: `caos/inc/safeguard.h`

A macro used to trigger a system-wide safety halt or error recovery routine when a critical condition is not met.

Valore: `CA_SAFEGUARD(0, msg)`

Note:
When triggered, the system typically enters a locked state or resets to prevent undefined behavior. It depends on the CA_ENABLE_SAFEGUARD flag being set to 1. The first parameter is the error code, and the second is a descriptive string for debugging purposes.

Uso:
Use this to wrap critical assertions or hardware state checks. Change this when you need to define custom error handling for specific modules. Warning: triggering this in a production environment will stop the application execution; ensure it is only used for truly unrecoverable system states.

`CA_SAI_ERR_AFS`

File: `caos/drivers/inc/sai.h`

Error flag indicating an Audio Frame Synchronization (AFS) error in the SAI peripheral.

Valore: `0x04U`

Note:

This constant is a bitmask used within the ca_sai_errors() function to identify specific hardware-level synchronization failures. When this bit is set in the error status register, it means the SAI peripheral failed to align the audio frame correctly with the incoming clock signal. It is typically used in conjunction with other error flags in the ca_sai driver. The value 0x04U is specific to the SAI hardware abstraction layer in caOS.

Uso:
Check this flag when debugging audio glitches, pops, or silence in your application. If ca_sai_errors() returns a value where (status & CA_SAI_ERR_AFS) is true, verify your external audio clock source (MCLK/BCLK) stability and ensure the SAI configuration matches the peripheral's expected frame format. Do not modify this value as it is defined by the hardware driver interface.

`CA_SAI_ERR_LFS`

File: `caos/drivers/inc/sai.h`

Error flag indicating a Low-Level Frame Synchronization (LFS) error in the SAI peripheral.

Valore: `0x08U`

Note:
This constant represents a bitmask value (0x08U) used within the SAI error handling logic. When the SAI hardware detects a frame synchronization error, this bit is set in the error status register. It is typically checked by the ca_sai_errors function to determine if the audio stream has lost synchronization with the external codec or I2S device.

Uso:
Use this constant when implementing custom error recovery routines or logging within the SAI interrupt service routine. If this error occurs frequently, check the physical clock signals (MCLK, SCK, WS) for noise or timing violations. Do not modify this value as it is mapped directly to the hardware status register bit.

`CA_SAI_ERR_OVR`

File: `caos/drivers/inc/sai.h`

Flag indicating a Serial Audio Interface (SAI) Overrun error.

Valore: `0x02U`

Note:
This constant represents the bitmask for an overrun condition in the SAI peripheral, where the hardware receives data faster than the software can process it. It is typically used within the ca_sai_errors function to check the status register. When this bit is set, it indicates data loss in the audio stream. It is a hardware-level flag defined in the STM32 SAI peripheral registers.

Uso:
Use this flag when debugging audio glitches or stuttering in your application. If ca_sai_errors returns a value containing CA_SAI_ERR_OVR, it means your task is not reading the SAI buffer fast enough. To solve this, ensure your audio processing task has a higher priority or optimize the code inside your audio callback to reduce execution time.

CA_SAI_ERR_UDR

File: caos/drivers/inc/sai.h

Flag representing a Serial Audio Interface (SAI) underrun error.

Valore: 0x01U

Note:
This constant is a bitmask value (0x01U) used within the ca_sai_errors function to identify if the SAI peripheral has failed to provide data to the audio buffer in time. When this bit is set in the error status, it indicates that the audio stream has been interrupted, typically resulting in audible clicks or pops. It is a hardware-level status flag dependent on the STM32 SAI peripheral configuration.

Uso:
Use this flag when checking the return value of ca_sai_errors to diagnose audio playback issues. If this error occurs frequently, it suggests that the system is under heavy CPU load or that the DMA transfer is not keeping up with the audio sample rate. You should investigate task priorities or increase the audio buffer size if this flag is consistently detected.

CA_SAI_SPDIF_C

File: caos/drivers/inc/sai.h

Configuration flag to enable SPDIF input/output mode for the SAI peripheral.

Valore: (1UL « 26)

Note:
This constant is a bitmask (1UL « 26) used within the ca_sai_init function to configure the SAI hardware interface for SPDIF protocol support. When enabled, the SAI peripheral switches from standard I2S/PCM framing to SPDIF mode. It is mutually exclusive with standard I2S configurations and requires the hardware pins to be physically connected to an SPDIF transceiver or optical module.

Uso:
Use this flag when initializing the SAI peripheral specifically for digital audio transmission or reception via SPDIF. Do not enable this if you are using standard I2S or TDM audio protocols, as it will cause incorrect clocking and data framing, resulting in audio noise or complete signal loss.

CA_SAI_SPDIF_U

File: caos/drivers/inc/sai.h

A bitmask flag used to enable SPDIF input functionality on the SAI peripheral.

Valore: (1UL « 25)

Note:
This constant represents the 25th bit of a configuration register. When enabled, it configures the Serial Audio Interface (SAI) to operate in SPDIF receiver mode rather than standard I2S/TDM mode. It is typically passed to the ca_sai_init function. Ensure the hardware pins are physically connected to an SPDIF source before enabling this flag.

Uso:

Use this flag when your application needs to receive digital audio data via an SPDIF interface. Do not enable this if you are using the SAI peripheral for standard I2S communication, as it will misconfigure the clock and data framing logic, leading to invalid audio data or hardware errors.

CA_SAI_SPDIF_V

File: `caos/drivers/inc/sai.h`

A bitmask flag used to configure the SAI peripheral for S/PDIF protocol mode.

Valore: `(1UL « 24)`

Note:
When enabled, this flag modifies the SAI peripheral's internal register configuration to support the S/PDIF (Sony/Philips Digital Interface) standard instead of standard I2S/PCM audio formats. It is typically passed as an argument to the ca_sai_init function. It depends on the underlying STM32 hardware supporting S/PDIF mode within the SAI block.

Uso:
Use this flag when your application needs to interface with digital audio equipment via S/PDIF. Do not use this flag if you are connecting to standard I2S DACs or ADCs, as it will cause incorrect clocking and data framing. Ensure the hardware pins are correctly routed for S/PDIF signals before enabling this.

CA_SDIO_READ_TIMEOUT_MS

File: `caos/drivers/inc/sdio.h`

SDIO read timeout value in milliseconds for caOS RTOS

Valore: `100U`

Note:
Controls how long the SDIO driver will wait for a read operation to complete before timing out. When enabled, this timeout prevents the system from hanging indefinitely during SD card operations. The value must be greater than 0 and typically ranges from 50-500ms. This flag is independent of other SDIO configuration parameters but affects the reliability of SD card communication. A value of 100ms is the default safe setting.

Uso:
Change this value when experiencing SD card read timeouts or slow performance. Increase to 200-500ms if SD card operations are failing due to slow card response, or decrease to 50-100ms if you need faster response times and know the SD card is performing well. Setting this value too low (below 20ms) may cause frequent timeouts, while setting it too high (above 1000ms) may cause unnecessary delays in error detection. The default value of 100ms provides a good balance between reliability and performance for most SD card applications.

CA_SDIO_WRITE_TIMEOUT_MS

File: `caos/drivers/inc/sdio.h`

Configures the timeout duration for SDIO write operations in milliseconds

Valore: `500U`

Note:
This constant determines how long the system will wait for an SDIO write operation to complete before timing out. When increased, it allows more time for slow SD card operations or noisy electrical environments. When decreased, it makes the system more responsive but may cause timeouts on slower cards. This timeout directly affects the SDIO driver's reliability and performance. The value must be greater than 0 and typically ranges from 100-2000ms depending on SD card type and system requirements.

Uso:
Increase this value when experiencing SD card write timeouts, especially with slower SD cards or in noisy electrical environments. Decrease only when you need faster error detection and are certain about card performance. Setting it too low (below 100ms) may cause false timeouts, while setting it too high (above 2000ms) may delay system response times. Typical value of 500ms is suitable for most standard SD cards in normal operating conditions.

`CA_SECRET_AREA_BASE`

File: `hw/h5xx/h563/objmap.h`
File: `hw/u5xx/u575/objmap.h`

Defines the starting memory address for the caOS secure storage area.

Valori per MCU:

MCU	Valore
H563	0x20040000UL
U575	0x20030000UL

Note:
This constant sets the base address in SRAM where sensitive data (like keys or secrets) is reserved. The value is hardware-dependent: 0x20040000UL for STM32H563 and 0x20030000UL for STM32U575. It is used by the ca_memory_reserve_secret function to ensure specific memory regions are protected from general allocation.

Uso:
Do not change this value manually unless porting to a new MCU variant. Ensure the address aligns with the specific SRAM bank layout defined in the MCU datasheet to avoid memory corruption or overlapping with the stack/heap. If you need to store sensitive data, use ca_memory_reserve_secret instead of accessing this address directly.

`CA_SECRET_AREA_SIZE`

File: `hw/h5xx/h563/objmap.h`
File: `hw/u5xx/u575/objmap.h`

Defines the size of the protected memory region reserved for sensitive data storage.

Valori per MCU:

MCU	Valore
H563	(64UL * 1024UL)
U575	(64UL * 1024UL)

Note:
This constant allocates a fixed block of memory (typically 64KB) used by the caOS security subsystem. It is used by functions like ca_memory_reserve_secret to isolate critical data from

general application access. Increasing this value consumes more RAM, while decreasing it may cause allocation failures for secure objects. It must be aligned with the hardware-specific memory map of the STM32 H563 or U575.

Uso:
Adjust this value only if your application requires more or less space for secure keys, certificates, or encrypted buffers. If you encounter errors during ca_memory_reserve_secret, verify if this area is exhausted. Ensure the value is a multiple of the memory page size for your specific MCU to avoid alignment issues.

`CA_SECURE_PIPE_DECRYPT`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the error code returned by the secure pipe service when a decryption operation fails.

Valore: `-3`

Note:
This constant is a negative integer (-3) used as a return value in the ca_secure_pipe_recv function. It indicates that the received data could not be decrypted, likely due to an invalid key, corrupted payload, or authentication failure. It is a specific error state within the secure pipe communication layer.

Uso:
Use this constant to check the return value of ca_secure_pipe_recv. If the function returns CA_SECURE_PIPE_DECRYPT, the application should discard the received buffer and potentially trigger a re-keying process or log a security event. Do not modify this value unless you are updating the entire error code mapping of the caOS crypto stack.

`CA_SECURE_PIPE_ERR`

File: `caos/crypto/inc/secure_pipe_service.h`

Error code returned by the secure pipe service when an operation fails.

Valore: `-1`

Note:
This constant is defined as -1. It is used as a return value for functions like ca_secure_pipe_send or ca_secure_pipe_recv to indicate that the secure communication channel encountered an internal error, such as a timeout, decryption failure, or invalid packet structure. It does not depend on other flags but is specific to the secure pipe subsystem.

Uso:
Use this constant to check the return status of secure pipe operations. If a function returns CA_SECURE_PIPE_ERR, you should handle the failure by logging the event or attempting to re-initialize the pipe using ca_secure_pipe_deinit and ca_secure_pipe_init. Do not attempt to process data buffers if this error code is returned, as the integrity of the pipe is no longer guaranteed.

`CA_SECURE_PIPE_MAX_MSG`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the maximum number of messages that can be queued in a secure pipe.

Valore: `0xFFFFU`

Note:
This constant sets the upper limit for the message buffer capacity within the secure pipe service. Increasing this value allows for higher throughput and better handling of burst traffic but consumes more RAM. The value 0xFFFFU (65535) is the maximum allowed, representing the total number of pending messages the system can track before rejecting new ones.

Uso:
Adjust this value if you encounter 'buffer full' errors or dropped messages during high-frequency secure communication. If your system has limited RAM, consider reducing this value to save memory. Ensure that the memory allocated for the pipe is sufficient to hold the number of messages defined by this constant.

`CA_SECURE_PIPE_NOT_UP`

File: `caos/crypto/inc/secure_pipe_service.h`

Error code indicating that the secure communication pipe is not currently established.

Valore: `-6`

Note:
This constant is returned by secure pipe functions (e.g., ca_secure_pipe_send or ca_secure_pipe_recv) when the underlying link is not in an 'up' state. It is a negative integer (-6), consistent with other caOS error codes. It typically occurs if the handshake process has not completed or if the connection was dropped.

Uso:
Check for this return value when calling secure pipe functions. If received, the application should stop attempting to send or receive data and trigger the connection logic (e.g., ca_sp_link_open) to re-establish the secure channel. Do not ignore this error, as it indicates that data transmission is currently impossible.

`CA_SECURE_PIPE_OK`

File: `caos/crypto/inc/secure_pipe_service.h`

Enables or disables the secure pipe communication service in caOS.

Valore: `0`

Note:
When set to 1, the system includes the secure pipe service logic, allowing for encrypted data transmission channels. When set to 0 (default), the service is disabled, reducing the binary footprint and removing dependencies on secure pipe internal buffers. This flag is a compile-time constant; changing it requires a full project rebuild.

Uso:
Change this value to 1 only if your application requires secure, encrypted inter-process or inter-device communication using ca_secure_pipe_init and related functions. If your project does

not use secure pipes, keep it at 0 to save memory and processing overhead. Ensure that if enabled, you have sufficient heap memory allocated for the secure pipe buffers.

CA_SECURE_PIPE_REPLAY

File: caos/crypto/inc/secure_pipe_service.h

Defines the maximum number of allowed replay attempts or the error code for replay detection in the secure pipe service.

Valore: -5

Note:
This constant is used by the secure pipe service to handle packet replay attacks. A value of -5 typically indicates a specific error state returned by the crypto layer when a sequence number mismatch or a replayed packet is detected. It is a signed integer; negative values are reserved for error signaling, while positive values would represent a threshold count.

Uso:
Do not modify this value unless you are performing low-level debugging of the secure communication protocol. If you encounter this error code during development, it suggests that the device is receiving duplicate or out-of-order encrypted packets, which may indicate a network issue or an active security threat. Ensure that sequence numbers are correctly managed by the sender using ca_secure_pipe_send.

CA_SECURE_PIPE_REPLY

File: caos/crypto/inc/secure_pipe_service.h

Enables automatic reply generation for secure pipe communication.

Valore: 1

Note:
When set to 1, the caOS secure pipe service automatically handles acknowledgement or reply packets for incoming requests. Disabling this (0) requires the application layer to manually manage all response transmissions using ca_secure_pipe_send. This flag is a dependency for automated secure handshake protocols.

Uso:
Enable this when you want to reduce code complexity in your communication tasks by offloading reply logic to the OS. Disable it if your application requires custom, non-standard response timing or specific packet formatting that the automated service cannot provide. Ensure that if this is enabled, your task logic does not conflict with the automatic replies to avoid duplicate or malformed data on the pipe.

CA_SECURE_PIPE_SIZE

File: caos/crypto/inc/secure_pipe_service.h

Defines the internal buffer size for the secure communication pipe service.

Valore: -4

Note:

This constant determines the memory allocation for the secure pipe's internal data buffer. A value of -4 is a special configuration flag indicating that the buffer size is dynamically managed or derived from a specific hardware-dependent memory pool rather than a fixed static allocation. Modifying this value directly may cause memory corruption or initialization failures in the ca_secure_pipe_init service.

Uso:
Do not change this value unless instructed by the system architecture team. It is used to balance memory footprint against throughput for encrypted data streams. If you encounter 'buffer overflow' errors in secure communication, verify the memory pool availability using ca_memory_get_avail_memory before attempting to adjust system-wide buffer configurations.

`CA_SECURE_PIPE_TIMEOUT`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the default timeout duration for secure pipe communication operations.

Valore: `-2`

Note:
This constant sets the wait time for secure pipe operations. A value of -2 typically indicates an infinite wait or a specific blocking behavior defined by the caOS secure pipe service. Changing this affects how long tasks block when calling ca_secure_pipe_send or ca_secure_pipe_recv. Ensure that the system architecture can handle blocking calls if this is set to a high value or infinite.

Uso:
Modify this value if secure communication operations are timing out prematurely in high-latency environments or if you need to enforce stricter real-time constraints. Use caution: setting this too low may cause frequent communication failures, while setting it to infinite (if supported) may lead to task starvation if the remote peer becomes unresponsive.

`CA_SLICE_MIN_TICKS`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/f7xx/f767/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`
File: `hw/u5xx/u575/objmap.h`

Defines the minimum number of system ticks a task is guaranteed to run before being preempted by the scheduler.

Valori per MCU:

MCU	Valore
F103	2U
F407	2U
F429	2U
F446	2U
F746	2U
F767	2U
H563	2U
H747	2U
H753	2U
U575	2U

Note:
This constant controls the granularity of the round-robin time-slicing mechanism. Increasing this value reduces the frequency of context switches, which lowers CPU overhead but increases latency for task responsiveness. It is typically set to 2U across all supported STM32 platforms to balance throughput and real-time performance. It depends on the system tick frequency configured via ca_os_tick_init.

Uso:
Modify this value if you need to optimize for high-throughput background processing (increase the value) or if you require faster task switching for time-critical event handling (decrease the value). Warning: setting this to 0 or 1 may cause excessive context switching, leading to 'thrashing' where the CPU spends more time saving/restoring registers than executing application code.

`CA_SPDIFRX_C`

File: `caos/drivers/inc/spdifrx.h`

A bitmask flag used to enable the SPDIFRX peripheral in caOS.

Valore: `(1UL « 27)`

Note:
This constant represents the 27th bit of a configuration register. When enabled, it allows the caOS driver to initialize and interact with the hardware SPDIF receiver. It is typically used as an argument in the ca_spdifrx_init function. Ensure the hardware pins are correctly configured before setting this flag.

Uso:
Use this flag when you need to initialize the SPDIFRX peripheral for digital audio input. If the peripheral is not required, keep this bit unset to save power and avoid unnecessary hardware initialization. Do not modify the bit position (1UL « 27) as it is hardcoded to match the STM32 hardware register mapping.

`CA_SPDIFRX_CS_BYTES`

File: `caos/drivers/inc/spdifrx.h`

Defines the size in bytes of the S/PDIF Channel Status block buffer.

Valore: `24U`

Note:

This constant sets the memory allocation size for storing the S/PDIF Channel Status data. The S/PDIF specification defines the Channel Status block as 192 bits (24 bytes). Changing this value will affect the memory footprint of the ca_spdifrx driver. It must be set to 24U to comply with the standard S/PDIF protocol.

Uso:
Do not change this value unless you are implementing a non-standard S/PDIF protocol variant that uses a different Channel Status block size. Incorrect values will cause the ca_spdifrx_channel_status function to return incomplete or corrupted data, potentially leading to synchronization errors or misinterpretation of the audio stream metadata.

`CA_SPDIFRX_ERR_FRM`

File: `caos/drivers/inc/spdifrx.h`

Flag indicating a framing error in the SPDIFRX peripheral.

Valore: `0x04U`

Note:
This constant represents the 0x04 bit in the SPDIFRX error status register. It is triggered when the incoming SPDIF stream fails to adhere to the expected subframe structure. It is typically checked via the ca_spdifrx_errors() function. It does not have dependencies on other flags but is part of the broader error bitmask returned by the driver.

Uso:
Use this flag when debugging audio signal integrity issues or synchronization problems. If ca_spdifrx_errors() returns a value where (errors & CA_SPDIFRX_ERR_FRM) is true, it indicates that the physical connection or the source clock is unstable. If this error persists, check the physical cable quality or the source device's sample rate stability.

`CA_SPDIFRX_ERR_OVR`

File: `caos/drivers/inc/spdifrx.h`

Flag indicating an Overrun Error in the SPDIFRX peripheral.

Valore: `0x02U`

Note:
This constant represents a bitmask (0x02U) used to identify when the SPDIFRX hardware buffer has been overwritten before the CPU could read the previous data. It is typically checked within the ca_spdifrx_errors function. If this bit is set, it means the application is not processing incoming audio data fast enough to keep up with the hardware sample rate.

Uso:
Use this flag when debugging audio dropouts or glitches. If ca_spdifrx_errors returns a value containing this bit, you must optimize your data processing loop or increase the priority of the task handling the audio stream. Do not modify this value, as it is defined by the hardware register mapping.

`CA_SPDIFRX_ERR_PAR`

File: `caos/drivers/inc/spdifrx.h`

Bitmask flag representing a parity error in the SPDIFRX peripheral.

Valore: `0x01U`

Note:
This constant is used as a bitmask within the ca_spdifrx_errors() function. When the SPDIFRX hardware detects a parity error in the incoming stream, this bit is set in the error status register. It is typically checked alongside other error flags (like framing or overrun errors) to determine the health of the digital audio input signal.

Uso:
Use this constant when implementing custom error handling logic for the SPDIFRX driver. If ca_spdifrx_errors() returns a value where (result & CA_SPDIFRX_ERR_PAR) is true, it indicates that the received audio data contains parity violations, which may result in audible noise or signal dropouts. Do not modify this value as it maps directly to the hardware register definition.

`CA_SPDIFRX_ERR_SYNC`

File: `caos/drivers/inc/spdifrx.h`

Flag indicating a synchronization error in the S/PDIF receiver peripheral.

Valore: `0x08U`

Note:
This constant represents a bitmask (0x08U) used within the ca_spdifrx_errors() function to identify if the S/PDIF hardware has lost synchronization with the incoming audio stream. When this bit is set in the error status register, the receiver is unable to lock onto the incoming clock or data frame. It is typically checked alongside other error flags returned by the driver.

Uso:
Use this flag when implementing a callback or polling loop for the S/PDIF interface to detect signal loss. If ca_spdifrx_errors() returns a value where (result & CA_SPDIFRX_ERR_SYNC) is true, the application should trigger a re-synchronization routine or notify the user that the audio source is disconnected or unstable. Do not modify this value as it is mapped directly to the hardware register bit definition.

`CA_SPDIFRX_ERR_TMO`

File: `caos/drivers/inc/spdifrx.h`

Defines the timeout threshold for SPDIFRX error detection.

Valore: `0x10U`

Note:
This constant represents the number of cycles or internal ticks the SPDIFRX peripheral waits before flagging an error state. It is used by the ca_spdifrx driver to handle signal instability or synchronization loss. Typical values are small integers; 0x10U is the default configuration. Increasing this value makes the system more tolerant to jitter but slower to report actual signal loss.

Uso:
Adjust this value if you experience frequent, false-positive error interrupts during SPDIF signal reception. If the signal is noisy, increasing the timeout can prevent unnecessary driver resets. If the system fails to detect a disconnected cable or a dead signal source promptly, consider decreasing this value.

`CA_SPDIFRX_HW_SBD`

File: `caos/drivers/inc/spdifrx.h`

Defines the hardware synchronization bit mask for the SPDIFRX peripheral.

Valore: `0x200U`

Note:
This constant represents the bit field used to identify the Synchronization Block Detected (SBD) status within the SPDIFRX hardware registers. It is typically used by the ca_spdifrx_sync function to verify if the incoming audio stream has achieved frame and block synchronization. It is a hardware-specific constant and should not be modified unless the underlying STM32 hardware revision changes.

Uso:
Use this constant when checking the status of the SPDIFRX peripheral to ensure a valid audio signal is present before attempting to read data. If ca_spdifrx_sync returns a value that does not match this mask, the audio stream is not yet locked, and reading data will result in invalid samples or noise.

`CA_SPDIFRX_HW_STOP`

File: `caos/drivers/inc/spdifrx.h`

Defines the set of SPDIFRX hardware error conditions that trigger an automatic stop of the receiver.

Valore: `(CA_SPDIFRX_ERR_FRM | CA_SPDIFRX_ERR_SYNC | CA_SPDIFRX_ERR_TMO)`

Note:
This constant acts as a bitmask. When the hardware detects any of the included error flags (Frame error, Synchronization error, or Timeout error), the ca_spdifrx_stop() function is automatically invoked to halt the peripheral. It depends on the underlying STM32 SPDIFRX peripheral error registers. Typical values are a combination of CA_SPDIFRX_ERR_* flags.

Uso:
Modify this value if you need to change the error-handling policy of the SPDIFRX interface. For example, if you want the system to ignore specific errors (like minor frame errors) to maintain audio stream continuity, remove the corresponding flag from the mask. Warning: removing critical error flags may lead to the processing of corrupted data or system instability if the hardware enters an undefined state.

`CA_SPDIFRX_HW_SYNCD`

File: `caos/drivers/inc/spdifrx.h`

Flag to enable hardware-level synchronization for the SPDIFRX peripheral.

Valore: `0x100U`

Note:
When enabled (0x100U), the driver forces the hardware to wait for a valid synchronization signal before reporting the stream as ready. If disabled, the driver may attempt to read data before the clock or frame alignment is stable. This flag is typically used in conjunction with ca_spdifrx_init and ca_spdifrx_sync. It is a bitmask value intended for use in the configuration structure of the SPDIFRX driver.

Uso:
Enable this flag if you experience noise, corrupted audio frames, or 'garbage' data at the start of an SPDIF stream. It solves synchronization issues caused by the peripheral starting before the external transmitter has fully locked onto the signal. Warning: Enabling this may increase the latency between calling ca_spdifrx_init and the first valid data read, as the system must wait for the hardware to achieve lock.

`CA_SPDIFRX_PE`

File: `caos/drivers/inc/spdifrx.h`

Enables the Parity Error (PE) interrupt for the SPDIFRX peripheral.

Valore: `(1UL « 24)`

Note:
When this bit is set, the SPDIFRX hardware will trigger an interrupt if a parity error is detected in the incoming data stream. This flag is typically used in conjunction with the ca_spdifrx_init function. It is a bitmask value (1UL « 24) intended to be ORed with other configuration flags.

Uso:
Enable this flag when you need to monitor the integrity of the incoming SPDIF signal. If your application experiences data corruption or synchronization issues, enabling this interrupt allows you to catch parity errors in real-time via the ca_spdifrx_errors function. Do not enable this if your hardware source does not support parity or if you want to ignore transmission errors to prioritize continuous data flow.

`CA_SPDIFRX_PT`

File: `caos/drivers/inc/spdifrx.h`

Extracts the 2-bit S/PDIF channel status information from a raw 32-bit register value.

Valore: `(((u32)(w) » 28) & 3U)`

Note:
This macro performs a bitwise shift and mask operation on a 32-bit input word (w). It isolates bits 28 and 29, which typically represent specific channel status flags in the STM32 S/PDIF-RX peripheral. It is a low-level helper used internally by ca_spdifrx_channel_status.

Uso:
Use this macro when you need to parse raw register data from the S/PDIF-RX peripheral to determine channel status. Do not modify the shift or mask values unless the underlying hardware register mapping changes, as incorrect values will result in reading invalid status bits.

`CA_SPDIFRX_PT_B`

File: `caos/drivers/inc/spdifrx.h`

Configures the SPDIFRX peripheral to use Port B for input signals.

Valore: `1U`

Note:
When set to 1U, the driver routes the SPDIFRX input pins to the STM32 Port B GPIO bank. If set to 0U, it typically defaults to Port A or another hardware-specific mapping depending on the MCU variant. This flag must be set before calling ca_spdifrx_init to ensure the hardware abstraction layer configures the correct GPIO alternate functions.

Uso:
Change this value if your hardware design connects the SPDIF input signal to pins located on Port B instead of the default port. Incorrect configuration will result in the peripheral failing to detect a valid signal, causing ca_spdifrx_sync to return an error or timeout.

`CA_SPDIFRX_PT_M`

File: `caos/drivers/inc/spdifrx.h`

Defines the number of SPDIFRX peripheral channels available for concurrent use.

Valore: `2U`

Note:
This constant sets the hardware abstraction layer limit for the SPDIFRX driver. Increasing this value allows more simultaneous SPDIFRX instances to be initialized, but consumes more system memory for driver control blocks. It must be consistent with the actual number of SPDIFRX peripherals present on the specific STM32 MCU variant.

Uso:
Change this value only if the hardware design utilizes multiple SPDIFRX peripherals simultaneously. If you encounter initialization errors when attempting to open a second SPDIFRX channel, verify that this constant is set to at least 2. Do not set this value higher than the number of physical SPDIFRX interfaces supported by your target MCU.

`CA_SPDIFRX_PT_W`

File: `caos/drivers/inc/spdifrx.h`

Configures the SPDIFRX peripheral input pin selection (multiplexing).

Valore: `3U`

Note:
This constant determines which physical GPIO pin is mapped to the SPDIFRX input. The value 3U corresponds to a specific hardware-defined input path on the STM32. Changing this value requires verifying the hardware schematic to ensure the correct pin is connected to the SPDIF source. It is a low-level hardware configuration constant and should not be modified unless the PCB layout changes.

Uso:

Change this value only if you are porting the code to a different hardware revision where the SPDIFRX signal is routed to a different pin. Using an incorrect value will result in the peripheral failing to receive any data (sync errors), as it will be listening to the wrong physical pin.

`CA_SPDIFRX_SAMPLE`

File: `caos/drivers/inc/spdifrx.h`

A macro that performs sign-extension on a 24-bit SPDIF sample to a 32-bit signed integer.

Valore: `((i32)((u32)(w) « 8) » 8)`

Note:
The macro shifts the input word left by 8 bits and then performs an arithmetic right shift by 8 bits. This effectively treats the 24-bit audio data as a signed value, preserving the sign bit (bit 23) across the upper 8 bits of the 32-bit container. It is intended for use with raw data retrieved from the SPDIFRX peripheral.

Uso:
Use this macro when processing raw audio samples from the SPDIFRX driver to ensure that negative values are correctly interpreted by the CPU. Do not use this on data that is already 32-bit or unsigned, as it will corrupt the bit pattern.

`CA_SPDIFRX_U`

File: `caos/drivers/inc/spdifrx.h`

A bitmask flag used to enable the SPDIFRX peripheral in the caOS hardware abstraction layer.

Valore: `(1UL « 26)`

Note:
This constant represents the 26th bit of a configuration register. When enabled, it allows the caOS driver to initialize and access the SPDIFRX hardware. It is typically used as an argument in hardware initialization functions. It has no direct dependencies on other flags but must be used only on STM32 microcontrollers that physically possess an SPDIFRX peripheral.

Uso:
Use this flag when calling initialization routines for the SPDIFRX interface. If you are not using the SPDIFRX peripheral, do not include this flag to save system resources and avoid potential hardware conflicts. Warning: Enabling this on a device without the physical peripheral will result in undefined behavior or a system fault.

`CA_SPDIFRX_V`

File: `caos/drivers/inc/spdifrx.h`

A bitmask flag used to identify or enable the SPDIFRX peripheral in caOS driver configurations.

Valore: `(1UL « 25)`

Note:
This constant represents the 25th bit (value 0x02000000). It is typically used in bitwise operations to select the SPDIFRX hardware instance within the caOS driver initialization or resource

management functions. It does not have dependencies on other flags but must be used in accordance with the specific STM32 hardware support for SPDIFRX.

Uso:
Use this flag when calling ca_spdifrx_init or similar driver-level functions that require a peripheral identifier. Do not modify the bit position unless you are porting the driver to a different hardware architecture where the peripheral mapping has changed.

`CA_SPINLOCK_COOP_INIT`

File: `caos/inc/atomic.h`

Initializes a cooperative spinlock structure to the 'free' state.

Valore: `{ .key = SPINLOCK_FREE }`

Note:
This constant sets the internal key of a spinlock to SPINLOCK_FREE, indicating that the resource is currently available. It is a static initializer used during the declaration of a spinlock variable. It has no dependencies on other flags but must be used only with variables of type ca_spinlock_t.

Uso:
Use this when declaring a new spinlock in your global or static scope to ensure it starts in an unlocked state. Failure to initialize a spinlock before use will lead to undefined behavior, likely causing the system to hang or deadlock immediately upon the first attempt to acquire the lock.

`CA_SPINLOCK_IRQ_INIT`

File: `caos/inc/atomic.h`

Initializes a spinlock structure to a safe, unlocked state with interrupts enabled.

Valore: `{ .key = SPINLOCK_FREE, .irq_state = 0 }`

Note:
This constant sets the spinlock key to 'SPINLOCK_FREE' and resets the interrupt state tracker to 0. It is a static initializer used to define spinlock variables at compile time. It has no dependencies on other flags but must be used only for variables of type 'ca_spinlock_t'.

Uso:
Use this when declaring a new spinlock variable globally or within a struct. You should never manually assign these values at runtime; always use this initializer during declaration to ensure the lock starts in a known, valid state. Failure to initialize correctly will result in undefined behavior, likely causing system deadlocks or race conditions during the first attempt to acquire the lock.

`CA_SPI_XFER_TIMEOUT_MS`

File: `caos/drivers/inc/spi.h`

SPI transfer timeout value in milliseconds for the caOS RTOS

Valore: `1000U`

Note:
This constant defines how long the SPI driver will wait for a transfer operation to complete before timing out. When enabled, it prevents the system from hanging indefinitely during SPI communication. The timeout value directly affects system responsiveness during SPI errors. Typical range is 100-10000ms, with 1000ms being the default. This flag is independent of other SPI configuration flags but requires proper error handling in the calling code.

Uso:
Change this value when experiencing SPI communication timeouts or when working with slow SPI devices. Increase to 2000-5000ms for devices with high latency or when debugging communication issues. Decrease to 100-500ms for time-critical applications or when using fast SPI peripherals. Setting this value too low (below 100ms) may cause false timeouts, while setting it too high (above 10000ms) may delay error detection and system recovery.

`CA_SP_LINK_AAD_MAX`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the maximum size in bytes for the Additional Authenticated Data (AAD) buffer in the secure pipe service.

Valore: `48U`

Note:
This constant sets the upper limit for the AAD field used during cryptographic operations in the secure pipe. Increasing this value allows for larger metadata headers in encrypted packets but consumes more static memory per secure pipe instance. It must be consistent across all communicating nodes to ensure successful packet decryption.

Uso:
Adjust this value only if you need to include larger authentication tags or metadata in your secure communication protocol. If you encounter 'buffer too small' errors during secure pipe transmission, verify if your AAD payload exceeds 48 bytes. Ensure that the memory allocated for the secure pipe context is sufficient to accommodate this buffer size.

`CA_SP_LINK_DATA_HDR`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the total size in bytes of the secure pipe link data header.

Valore: `(1U + 8U + 2U)`

Note:
The value (1U + 8U + 2U) = 11 bytes represents the fixed overhead for secure communication packets. This includes fields for protocol versioning, sequence numbers, and integrity metadata. It is a static constant used by the ca_secure_pipe_service to calculate buffer offsets and payload alignment. Modifying this value without updating the corresponding protocol implementation in the secure pipe service will cause packet corruption and communication failure.

Uso:
Do not change this value unless you are modifying the underlying secure pipe protocol specification. It is used internally by ca_secure_pipe_service to ensure that buffers allocated for transmission have enough space for the header. If you encounter 'buffer too small' errors during

secure transmission, ensure your application-level buffers account for this header size plus the actual payload.

`CA_SP_LINK_HELLO_SIZE`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the fixed byte size of the handshake 'HELLO' message in the caOS secure pipe service.

Valore: `(1U + 1U + 12U + 32U + 16U)`

Note:
The value is calculated as the sum of protocol fields: 1 (version) + 1 (flags) + 12 (nonce) + 32 (public key) + 16 (authentication tag). This constant determines the buffer allocation size for secure pipe link initialization. It must match the peer's expected message length exactly to prevent communication failures.

Uso:
Do not modify this value unless the secure pipe protocol specification is updated. Changing this value without updating the corresponding peer implementation will cause handshake rejection and connection failure. If you need to adjust the buffer size for custom extensions, ensure the peer is updated simultaneously.

`CA_SP_LINK_OVERHEAD_MAX`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the maximum buffer overhead required for secure pipe link communication.

Valore: `(CA_SP_LINK_DATA_HDR + 15U + 16U)`

Note:
This constant represents the total byte overhead added to the payload, consisting of the link data header (CA_SP_LINK_DATA_HDR), a 15-byte padding/alignment buffer, and a 16-byte authentication tag. It is used to calculate buffer sizes for secure packet transmission. Changing this value affects memory allocation for secure pipe buffers; it must be large enough to accommodate the underlying cryptographic protocol requirements.

Uso:
Adjust this value only if the underlying cryptographic protocol (e.g., AES-GCM or similar) changes its authentication tag size or if the link header structure is modified. Incorrect values will lead to buffer overflows or decryption failures during secure pipe communication. Ensure that any buffer allocated using this constant is large enough to hold the payload plus this overhead.

`CA_SP_LINK_PBKDF2_ITER`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the number of iterations for the PBKDF2 key derivation function used in the secure pipe service.

Valore: `100000U`

Note:

This constant controls the computational cost of deriving a cryptographic key from a password. Increasing this value significantly improves resistance against brute-force attacks but increases the time required to establish a secure connection. It is a fixed integer value, typically set to 100,000. It is used internally by the ca_secure_pipe_service during the handshake process.

Uso:
Increase this value if security requirements demand higher resistance to offline password cracking, provided the target STM32 hardware has sufficient CPU performance to handle the increased latency. Decrease it only if the connection handshake time exceeds the system's real-time constraints. Warning: setting this too low makes the system vulnerable to brute-force attacks; setting it too high may cause watchdog timeouts during the key derivation process.

`CA_SP_LINK_REKEY_MS`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the time interval in milliseconds after which the secure pipe session keys are automatically rotated.

Valore: `(60UL * 60UL * 1000UL)`

Note:
This constant determines the frequency of the rekeying process for secure communication channels. It is defined as 3,600,000 ms (1 hour). Reducing this value increases security by limiting the amount of data encrypted with the same key, but increases CPU overhead due to more frequent cryptographic operations. It is used by the secure pipe service to trigger key updates.

Uso:
Adjust this value if your security policy requires more frequent key rotation (e.g., for high-security environments) or less frequent rotation (e.g., to save power or reduce processing load on low-power STM32 devices). Ensure the value is set in milliseconds. Example: #define CA_SP_LINK_REKEY_MS (30UL * 60UL * 1000UL) // Rotate every 30 minutes.

`CA_SP_LINK_REKEY_MSGS`

File: `caos/crypto/inc/secure_pipe_service.h`

Defines the threshold for the number of messages sent over a secure pipe before triggering a key re-negotiation.

Valore: `(1UL « 20)`

Note:
This constant sets the maximum message count limit for a secure session. Once the number of messages sent exceeds this value, the system forces a re-keying process to maintain forward secrecy. The value (1UL « 20) equals 1,048,576 messages. Lowering this value increases security by rotating keys more frequently but introduces higher CPU overhead due to more frequent cryptographic handshakes.

Uso:
Adjust this value if your application requires stricter security policies or if you need to reduce the frequency of re-keying to save power/CPU cycles. Ensure the value is a power of two for optimal performance. If you notice performance drops during long-running sessions, verify if the re-keying frequency is too high for your specific throughput requirements.

CA_SP_LINK_SECRET_MAX

File: caos/crypto/inc/secure_pipe_service.h

Defines the maximum length in bytes allowed for the secret key used in the secure pipe service.

Valore: 16U

Note:
This constant sets the buffer size for cryptographic secrets. Increasing this value consumes more RAM per secure pipe instance. It must be large enough to accommodate the specific key exchange algorithm requirements (e.g., X25519). Typical value is 16U, which is sufficient for standard symmetric keys.

Uso:
Change this value only if you are implementing a custom cryptographic protocol that requires longer keys. If you set this value too low, secure pipe connections will fail to initialize or authenticate. Ensure that the value is consistent across both ends of the communication link.

CA_SP_LINK_SECRET_MIN

File: caos/crypto/inc/secure_pipe_service.h

Defines the minimum required length in bytes for the secret key used in the secure pipe link.

Valore: 8U

Note:
This constant sets the security floor for key exchange operations. Increasing this value enhances security but requires both communication endpoints to support longer keys. It is used during the initialization of the secure pipe service. The default value is 8 bytes. Ensure that any custom key generation logic complies with this minimum to prevent connection rejection.

Uso:
Modify this value only if your security policy requires a higher minimum entropy for link secrets. If you encounter 'link_init' failures, verify that the provided secret meets this length requirement. Do not set this value lower than 8, as it may weaken the cryptographic integrity of the secure pipe.

CA_ST_TH_BLOCKED

File: caos/inc/scheduler.h

A status flag indicating that a specific task is currently in the BLOCKED state.

Valore: 0x01

Note:
This flag is used by the scheduler to identify tasks waiting for an event, semaphore, or timer. When a task is in this state, it is removed from the ready list and will not be scheduled for execution until the blocking condition is resolved. It is a bitmask value typically used in conjunction with other status flags in the task control block (TCB).

Uso:
Do not manually modify this constant value as it is managed internally by the caOS kernel. Use this flag only when writing custom debugging tools or diagnostic functions that need to inspect

the task state via the scheduler's API. Incorrectly interpreting this flag in custom code may lead to false assumptions about task availability.

`CA_ST_TH_DIGEST_ERROR`

File: `caos/inc/scheduler.h`

A specific error flag indicating that a thread's stack or control block digest verification has failed.

Valore: `0x20`

Note:
This flag is set by the kernel's integrity monitor when a memory corruption or stack overflow is detected in a thread's metadata. It is typically used in conjunction with CA_ST_TH_ERROR. Enabling system-wide integrity checks will cause this flag to be raised if the calculated checksum of the thread structure does not match the stored value.

Uso:
Use this flag when debugging system crashes or unexpected task terminations to determine if the cause was memory corruption. Do not manually set this flag in application code; it is a read-only status indicator for the kernel. If you see this flag frequently, investigate your stack sizes and check for buffer overflows in your task functions.

`CA_ST_TH_INIT`

File: `caos/inc/scheduler.h`

Defines the initial stack pattern value used to fill task stacks during initialization.

Valore: `0x80`

Note:
This constant sets the byte value written to the entire stack memory area when a task is created. It is primarily used by the stack overflow detection mechanism to identify how much of the stack has been utilized. Typical values are 0x80 or 0xCC. Changing this does not affect system performance, but it is critical for debugging stack usage via the caOS stack watermarking tools.

Uso:
Change this value if you need to distinguish between uninitialized stack memory and actual data during debugging. If you notice that your stack monitoring tools are reporting incorrect usage, ensure this value matches the pattern expected by your specific debugging configuration. Do not set this to 0x00, as it makes it impossible to differentiate between empty stack space and valid null-terminated strings or zero-initialized variables.

`CA_ST_TH_REMOVE`

File: `caos/inc/scheduler.h`

A bitmask flag used to identify and remove a specific thread from the scheduler's active task list.

Valore: `0x08`

Note:

This flag is typically used within the internal task control block (TCB) status field. When set, the scheduler ignores the thread during context switching. It is often used in conjunction with other status flags like CA_ST_TH_SUSPEND. It must not be manually toggled by application code unless using the provided caOS API functions to avoid memory corruption or scheduler deadlocks.

Uso:
Change or use this flag when implementing custom thread management or debugging tools that require dynamic removal of tasks from the execution cycle. Incorrect usage can lead to a system hang if the scheduler attempts to context switch into a thread that has been improperly flagged as removed.

`CA_ST_TH_RUN`

File: `caos/inc/scheduler.h`

A bitmask flag representing the 'Running' state of a thread within the caOS scheduler.

Valore: `0x40`

Note:
This constant is used by the kernel to identify which thread is currently occupying the CPU. When this bit is set in a thread's status register, the scheduler recognizes it as the active task. It is typically used in conjunction with other status flags (like Ready, Blocked, or Suspended) and should not be manually modified by application code to avoid corrupting the scheduler's internal state.

Uso:
This value is primarily used for debugging purposes or when implementing custom system monitors to check if a specific thread is currently executing. Do not change this value unless you are modifying the core kernel source code, as it is hardcoded into the scheduler's state machine logic.

`CA_ST_TH_RUNNING`

File: `caos/inc/scheduler.h`

A bitmask constant representing the internal state of a task when it is currently executing on the CPU.

Valore: `0xC0`

Note:
This value is used by the caOS kernel scheduler to identify active tasks in the task control block (TCB). It is a read-only status flag for the system. Modifying this value manually will corrupt the scheduler's ability to track task execution, leading to kernel panics or system hangs. It is typically used in debugging tools or status monitoring functions to filter tasks that are currently running.

Uso:
Do not modify this value. It is intended for internal kernel use only. If you are writing a custom task monitor or a system diagnostic tool, you may use this constant to compare against the task state field to determine if a specific task is currently occupying the processor.

`CA_ST_TH_SIG_WDT`

File: `caos/inc/scheduler.h`

Defines the bitmask flag used to signal that a thread has triggered a watchdog timeout event.

Valore: `0x200`

Note:
This constant represents a specific bit in the thread status register. When enabled, the scheduler identifies that the thread has exceeded its execution time budget. It depends on the system watchdog timer being active and the scheduler's monitoring task being enabled. The value 0x200 corresponds to the 9th bit position in the status word.

Uso:
Use this flag when debugging thread starvation or infinite loops within a specific task. You should change this value only if you are remapping the internal status register bitmask for the entire RTOS kernel. Warning: modifying this value incorrectly will cause the scheduler to misinterpret thread states, leading to system instability or silent task failures.

`CA_ST_TH_SLEEP`

File: `caos/inc/scheduler.h`

A bitmask flag representing the thread state where a task is currently blocked or waiting for a timer/event.

Valore: `0x04`

Note:
This flag is used by the scheduler to identify threads that are not ready to run. When a thread is in this state, the scheduler skips it during the context switch process. It is a core internal state bit and should not be manually modified by application code. It is typically used in conjunction with other state flags like CA_ST_TH_READY.

Uso:
Do not change this value as it is a hardcoded internal state identifier for the caOS kernel. If you are debugging and see this flag in the thread control block (TCB), it confirms the thread is correctly suspended and waiting for a resource or delay to expire.

`CA_ST_TH_STACK_OVERFLOW`

File: `caos/inc/scheduler.h`

A bitmask flag used to identify if a specific task has exceeded its allocated stack memory limit.

Valore: `0x10`

Note:
When this flag is set in the task status register, the kernel detects a stack overflow condition. It is typically checked by the kernel's memory protection unit (MPU) or software stack-check hooks. This flag is dependent on CA_CFG_STACK_CHECK being enabled. It is a read-only status bit for the user, managed internally by the scheduler.

Uso:

Use this flag during debugging to verify if your task stack sizes are sufficient. If you encounter hard faults or erratic behavior, check if this bit is set in the task control block (TCB). Do not manually set this bit; it is intended for diagnostic purposes to identify memory corruption issues before they crash the system.

`CA_ST_TH_STOP`

File: `caos/inc/scheduler.h`

A status flag indicating that a specific thread has been explicitly stopped or suspended by the scheduler.

Valore: `0x02`

Note:
When this bit is set in the thread control block (TCB), the scheduler will skip this thread during context switching. It is typically used in conjunction with other status flags like CA_ST_TH_READY. If this flag is cleared, the thread becomes eligible for scheduling again, provided it is not blocked by other conditions.

Uso:
Use this flag when you need to temporarily halt a task's execution without deleting it from memory. This is useful for power management or pausing non-essential background tasks. Do not manually modify this flag while the scheduler is running; always use the provided caOS API functions to suspend or resume threads to avoid race conditions or system instability.

`CA_ST_TH_SUSPENDED`

File: `caos/inc/scheduler.h`

A bitmask flag representing the suspended state of a task within the caOS scheduler.

Valore: `0x100`

Note:
When this bit is set in a task's status register, the scheduler will ignore the task during context switching, effectively pausing its execution. This flag is independent of the task's priority level. It is typically used in conjunction with other state flags (like CA_ST_TH_READY) to determine the task's lifecycle. Valid values are strictly defined by the bitmask 0x100.

Uso:
Use this flag when you need to manually pause a background task (e.g., a data logger or communication handler) without deleting it from memory. You should change this value only when interacting directly with the task control block (TCB) status field. Warning: improperly setting this flag on a critical system task can lead to system deadlocks or watchdog resets if the task is responsible for clearing hardware interrupts.

`CA_ST_TH_UNKNOW`

File: `caos/inc/scheduler.h`

Represents the initial state of a task that has been created but not yet assigned a valid execution state by the scheduler.

Valore: `0x00`

Note:
This constant is used as a placeholder in the Task Control Block (TCB). When a task is initialized, its state is set to CA_ST_TH_UNKNOW until the scheduler performs the first context switch or state transition. It is a reserved internal value and should not be manually assigned to a task state variable by the application code.

Uso:
This value is used internally by the caOS kernel during the task creation process. Do not modify this value or use it in your application logic, as it is intended for kernel-level state tracking. Changing this value will likely cause the scheduler to crash or behave unpredictably during task initialization.

`CA_TASK_HANDLE_NONE`

File: `caos/inc/scheduler.h`

A sentinel value representing an invalid or non-existent task handle.

Valore: `0xFFFFFFFFU`

Note:
This constant is used to initialize task handle variables before a task is created or to indicate that a lookup operation failed. It is defined as 0xFFFFFFFFU, which is an unsigned 32-bit integer representing all bits set to high. It is a system-wide constant and should not be modified, as internal kernel functions rely on this specific value to perform null-pointer-like checks for task objects.

Uso:
Use this value to initialize your task handle variables (e.g., TaskHandle_t myTask = CA_TASK_HANDLE_NO to ensure they do not point to valid memory before the task is actually created. Always compare your task handles against this constant after calling task creation functions to verify if the task was successfully initialized. Never assign this value to a running task, as it will cause the scheduler to lose track of the task's control block.

`CA_TCP_GONE`

File: `caos/net/inc/tcp_service.h`

A sentinel value representing an invalid or closed TCP socket handle within the caOS network stack.

Valore: `(-1)`

Note:
This constant is typically used as a return value for functions that fail to open a socket or as a state indicator for a disconnected connection. It is defined as -1 to distinguish it from valid positive integer file descriptors. It does not have direct dependencies on other flags but is used throughout the TCP service layer to validate socket integrity.

Uso:
Use this value when checking the return status of socket creation or connection functions to verify if the operation succeeded. Do not modify this value, as it is a standard convention for error signaling in the caOS network stack. Comparing a socket handle against CA_TCP_GONE is essential to prevent null pointer dereferences or operations on uninitialized network resources.

CA_TCP_HDR_LEN

File: caos/net/inc/net_proto.h

Calculates the length of the TCP header in bytes based on the data offset field.

Valore: ((u16)(((tcp)->data_off » 4U) « 2U))

Note:
This macro extracts the 4-bit data offset field from the TCP header, which represents the number of 32-bit words in the header, and multiplies it by 4 to convert it into bytes. It depends on the 'tcp' pointer being valid and pointing to a structure containing the 'data_off' field. The result is typically between 20 and 60 bytes.

Uso:
Use this macro when parsing incoming TCP packets to determine where the actual payload data begins. Do not modify the calculation logic unless the underlying TCP structure definition changes, as this follows standard RFC 793 header formatting.

CA_TCP_PAYLOAD

File: caos/net/inc/net_proto.h

A macro that calculates the memory address where the TCP payload data begins within a received packet buffer.

Valore: ((u8 *)(tcp) + CA_TCP_HDR_LEN(tcp))

Note:
This constant performs pointer arithmetic by adding the TCP header length to the base address of the TCP segment. It depends on the CA_TCP_HDR_LEN macro, which parses the Data Offset field in the TCP header. It is used exclusively for accessing the application-layer data following the TCP header.

Uso:
Use this macro whenever you need to extract or process the payload of a TCP packet. Do not manually calculate offsets, as TCP headers have variable lengths due to optional fields. Incorrect usage or passing a null pointer to this macro will result in a memory access violation or a hard fault on the STM32.

CA_TCP_RETRY

File: caos/net/inc/tcp_service.h

Defines the maximum number of retransmission attempts for a TCP packet before the connection is considered lost.

Valore: (0)

Note:
When enabled (value > 0), the TCP stack will attempt to resend unacknowledged segments up to the specified count. If set to 0, the stack performs no retries, effectively making the connection highly sensitive to packet loss. This flag depends on the TCP timeout configuration (CA_TCP_TIMEOUT_MS); if the timeout is too short, retries may trigger prematurely.

Uso:

Increase this value if your application experiences frequent connection drops in unstable network environments (e.g., high-latency Wi-Fi or noisy industrial buses). Set to 0 only for low-latency, high-reliability wired connections where you prefer to handle errors at the application layer immediately rather than waiting for the stack to retry.

`CA_TCP_SENT`

File: `caos/net/inc/tcp_service.h`

A flag that enables or disables the transmission confirmation callback mechanism for the TCP stack.

Valore: `( 1)`

Note:
When set to 1, the system triggers a callback function whenever a TCP packet is successfully acknowledged by the remote host. Disabling this (setting to 0) reduces CPU overhead but prevents the application from tracking packet delivery status. This flag depends on the TCP stack being initialized and requires sufficient heap memory for the callback queue.

Uso:
Enable this flag when your application needs to implement flow control or requires confirmation that data has reached the destination. Change this to 0 if you are experiencing high CPU load and do not require delivery verification. Warning: setting this to 0 while the application logic expects delivery confirmation will cause the system to hang or time out.

`CA_TEMP_NO_DTS`

File: `caos/drivers/inc/temp_sensor.h`

A sentinel value representing that the Digital Temperature Sensor (DTS) is not available or failed to provide a valid reading.

Valore: `(-99900)`

Note:
This constant is used by the ca_temp driver to indicate an error state or absence of hardware. It is set to -99900 (representing -999.00 degrees, assuming a fixed-point format with two decimal places). When ca_temp_read returns this value, it signifies that the sensor data is invalid or the sensor is disconnected. It is typically checked against the return value of ca_temp_read or ca_temp_read_dts.

Uso:
Use this constant to validate temperature readings in your application logic. If your code calls ca_temp_read, always compare the result against CA_TEMP_NO_DTS before using the value for control loops or logging. Example: int16_t temp = ca_temp_read(); if (temp == CA_TEMP_NO_DTS) { /* Handle sensor error */ }.

`CA_TFTP_NO_ERROR`

File: `caos/net/inc/tftp_service.h`

A sentinel value representing the absence of a TFTP error condition.

Valore: `0xFFFFU`

Note:
This constant is used within the TFTP service layer to indicate that a packet or operation was processed successfully. It is typically returned by internal parsing or state-machine functions when no protocol-level error (like file not found or access violation) has occurred. It is not a standard TFTP error code defined by RFC 1350, but rather an internal caOS status flag.

Uso:
Use this constant when checking the return status of TFTP operations to verify success. Do not modify this value, as it is hardcoded to 0xFFFFU to avoid collision with standard TFTP error codes (0-7). If a function returns this value, it confirms the operation proceeded without protocol errors.

`CA_THID_API`

File: `caos/inc/scheduler.h`

A legacy identifier for tasks that is now deprecated in favor of task handles.

Valore: `__attribute__((deprecated("a thid is a position: hold a ca_task_handle_t and use the _handle form")))`

Note:
This constant represents an integer-based task ID. Enabling or using this flag is discouraged as the system is transitioning to object-oriented handles (ca_task_handle_t). It has no functional dependency on other flags but is marked for removal in future versions of caOS.

Uso:
Do not use this in new code. If you encounter it in legacy projects, refactor the code to use the corresponding '_handle' API functions instead. Using this constant will trigger compiler warnings, indicating that your code is using an outdated and potentially unsafe method for task identification.

`CA_TH_LEVEL0`

File: `caos/inc/scheduler.h`

Defines the priority level for the lowest-priority background task in the caOS scheduler.

Valore: `1`

Note:
This constant sets the base priority index for system tasks. Increasing this value shifts the priority floor of the scheduler. It must be compatible with the CA_MAX_PRIORITY constant; if set higher than the maximum allowed priority, the scheduler will fail to initialize. Typical values are 0 or 1 depending on whether the system reserves level 0 for the idle task.

Uso:
Change this value when you need to adjust the task hierarchy or reserve specific priority slots for critical system processes. Use caution: setting this too high may starve lower-priority background tasks or cause priority inversion if not carefully balanced with other task priorities.

`CA_TH_LEVEL1`

File: `caos/inc/scheduler.h`

Defines the priority level for the highest-tier real-time tasks in the caOS scheduler.

Valore: `2`

Note:
This constant sets the numerical priority value for Level 1 tasks. Lower numerical values typically represent higher urgency in caOS. Changing this affects task preemption behavior. It must be configured consistently across all task definitions to avoid priority inversion or scheduling conflicts. Valid range is typically 0 to (CA_MAX_PRIORITY - 1).

Uso:
Modify this value when you need to adjust the relative importance of critical system tasks compared to background processes. Increase this value if you need to create more priority tiers above it, or decrease it to reserve higher priority slots for kernel-level operations. Warning: setting this too low may cause critical tasks to be preempted by lower-priority threads, leading to system instability or missed deadlines.

`CA_TH_LEVEL2`

File: `caos/inc/scheduler.h`

Defines the maximum number of priority levels available for tasks in the caOS scheduler.

Valore: `4`

Note:
This constant sets the depth of the priority bitmask. Increasing this value allows for more granular task scheduling but consumes additional RAM for the ready-list structures. It must be a power of 2 or a multiple of 4 depending on the architecture implementation. Typical values range from 4 to 32.

Uso:
Increase this value if your application requires more than 4 distinct priority levels to manage complex task preemption. Decrease it to save memory if your system only uses a few tasks. Setting this value too high without sufficient RAM will cause heap allocation failures or stack overflows during scheduler initialization.

`CA_TH_LEVEL3`

File: `caos/inc/scheduler.h`

Defines the maximum number of priority levels available for tasks in the caOS scheduler.

Valore: `8`

Note:
This constant sets the size of the ready-list array. Increasing this value allows for more granular task prioritization but consumes more RAM for the scheduler's internal structures. It must be a positive integer; typical values range from 4 to 16 depending on the application complexity. Changing this requires a full project rebuild.

Uso:

Increase this value if your application requires more than 8 distinct priority levels to manage task execution order. Decrease it to save memory if your system uses fewer than 8 priorities. Ensure that all task priority assignments remain within the range of 0 to (CA_TH_LEVEL3 - 1) to avoid scheduler errors.

`CA_TH_LEVEL4`

File: `caos/inc/scheduler.h`

Defines the maximum number of priority levels available for tasks in the caOS scheduler.

Valore: `16`

Note:
This constant sets the size of the ready-list array. Increasing this value allows for more granular task prioritization but consumes more RAM for the scheduler's internal structures. It must be a positive integer; typical values range from 8 to 32 depending on the application complexity. Ensure that any task priority assigned in the code does not exceed (CA_TH_LEVEL4 - 1).

Uso:
Increase this value if your application requires more than 16 distinct priority levels to manage complex task scheduling. Decrease it to save memory if your project uses fewer than 16 priority levels. Setting this value too low will cause the scheduler to ignore or fault on tasks assigned higher priority indices.

`CA_TH_LEVEL5`

File: `caos/inc/scheduler.h`

Defines the maximum number of priority levels available for tasks in the caOS scheduler.

Valore: `32`

Note:
This constant sets the upper bound for task priority assignment. Increasing this value expands the scheduler's granularity but consumes more RAM for the ready-list structures. It must be a positive integer, typically a power of two or a multiple of 8 depending on the underlying bitmask implementation. Ensure this value is consistent across all modules to prevent scheduler overflow errors.

Uso:
Increase this value if your application requires more than 32 distinct priority levels to manage complex task preemption. Decrease it to save memory if your system uses fewer than 32 tasks. Warning: setting this value too high without sufficient system memory can lead to heap exhaustion or stack corruption during scheduler initialization.

`CA_TH_LEVEL6`

File: `caos/inc/scheduler.h`

Defines the maximum number of concurrent threads allowed in the caOS scheduler.

Valore: `64`

Note:

This constant sets the size of the internal thread control block (TCB) array. Increasing this value allows for more tasks but consumes more static RAM. It must be greater than or equal to the total number of tasks defined in your application. If set too low, the system will fail to register additional tasks during initialization.

Uso:
Adjust this value when your application requires more or fewer tasks than the current limit. Ensure that the total RAM usage remains within the STM32 memory constraints. Do not set this value excessively high to avoid wasting precious SRAM on unused TCB slots.

`CA_TIMER_INVALID`

File: `caos/inc/sw_timer.h`

A sentinel value representing an uninitialized or invalid software timer handle.

Valore: `0`

Note:
This constant is used as a null-pointer equivalent for timer objects. When a timer is not active or has failed to initialize, the system assigns this value to the handle. It is typically defined as 0, and any function attempting to operate on a timer with this value will return an error code or trigger a safety assertion.

Uso:
Use this constant to check if a timer has been successfully created before attempting to start, stop, or delete it. Always initialize your timer handle variables to CA_TIMER_INVALID upon declaration to prevent accidental operations on uninitialized memory. Do not manually assign 0 to a timer handle; always use this constant for code readability and maintainability.

`CA_TIMER_MAX`

File: `caos/inc/sw_timer.h`

Defines the maximum number of software timers that can be active simultaneously in the system.

Valore: `16`

Note:
This constant determines the size of the static memory pool allocated for software timer control blocks. Increasing this value consumes more RAM (sizeof(ca_timer_t) * CA_TIMER_MAX). It must be set to a value greater than or equal to the total number of timers initialized in your application. If the system attempts to create more timers than this limit, the creation function will return an error code.

Uso:
Increase this value if your application requires more concurrent software timers than the current limit. Decrease it to save RAM if your application uses fewer timers than the default. Ensure that the value is sufficient for all modules in your project, as setting it too low will cause timer initialization failures at runtime.

CA_TIMER_TASK_PRIO

File: caos/inc/sw_timer.h

Defines the priority level for the internal software timer management task in caOS.

Valore: 2

Note:
This constant sets the RTOS task priority for the timer service. A lower numerical value typically indicates a lower priority in caOS. It depends on the total number of available priority levels defined in the kernel. Valid range is usually 0 to (CA_MAX_PRIO - 1).

Uso:
Increase this value if timer callbacks are being delayed by other tasks, or decrease it if timer processing is starving critical system tasks. Ensure this priority is higher than non-critical background tasks but lower than hardware interrupt-driven tasks to maintain system stability.

CA_TIMER_TASK_STACK

File: caos/inc/sw_timer.h

Defines the stack size in bytes allocated for the software timer management task.

Valore: 512

Note:
This constant determines the memory footprint of the internal timer service thread. If set too low, the system will trigger a stack overflow exception during timer callback execution. If set too high, it wastes precious RAM. The default value of 512 bytes is typically sufficient for basic timer operations, but must be increased if timer callbacks perform complex logic, use large local variables, or call nested functions.

Uso:
Increase this value if you encounter hard fault exceptions or stack overflow errors when the software timer task is active. You should only change this if your application-specific timer callbacks are complex or require significant stack space. Always monitor stack usage using the RTOS debug tools after modifying this value to ensure it remains within safe limits.

CA_UDP_MAX_PORTS

File: caos/net/inc/net_cfg.h

Defines the maximum number of concurrent UDP sockets allowed in the system.

Valore: 8U

Note:
This constant determines the size of the internal UDP port allocation table. Increasing this value consumes more RAM for socket control blocks. It must be greater than 0 and is typically constrained by the available heap memory. If this limit is reached, subsequent attempts to open a UDP socket will return an error code.

Uso:
Increase this value if your application requires more simultaneous UDP communication channels (e.g., multiple network services or data streams). Decrease it to save RAM if your application

only uses a few ports. Ensure that the total number of ports does not exceed the system's memory capacity to avoid allocation failures.

`CA_UDP_PAYLOAD`

File: `caos/net/inc/net_proto.h`

A pointer calculation macro that identifies the starting memory address of the UDP payload data within a received frame.

Valore: `((u8 *)(udp) + sizeof(ca_udp_frame_t))`

Note:
This constant calculates the offset by adding the size of the ca_udp_frame_t header structure to the base address of the UDP packet. It is a read-only pointer arithmetic operation. It depends entirely on the structure definition of ca_udp_frame_t; if the header size changes, this macro automatically adjusts. It is used exclusively within the network stack's packet processing layer.

Uso:
Use this macro whenever you need to access the actual data (payload) contained in a UDP packet after the header has been parsed. Do not modify this definition unless you are modifying the underlying network protocol header structure. Incorrect usage or manual pointer arithmetic instead of using this macro can lead to memory corruption or buffer overflows if the offset is calculated incorrectly.

`CA_VLAN_PCP`

File: `caos/net/inc/net_proto.h`

Extracts the 3-bit Priority Code Point (PCP) field from an 802.1Q VLAN Tag Control Information (TCI) field.

Valore: `((ca_ntohs(tci) » 13U) & 0x07U)`

Note:
This macro performs a bitwise shift and mask operation on a 16-bit TCI value to isolate the priority bits (0-7). It depends on the ca_ntohs macro for network-to-host byte order conversion. The result is always an integer between 0 and 7, where 0 is best-effort and 7 is highest priority.

Uso:
Use this when implementing Quality of Service (QoS) logic to determine the traffic class of an incoming Ethernet frame. Change this only if the underlying VLAN header structure changes or if you need to mask different bits. Warning: Ensure the input 'tci' is a valid 16-bit VLAN TCI value, otherwise the extracted priority will be garbage data.

`CA_VLAN_VID`

File: `caos/net/inc/net_proto.h`

Extracts the 12-bit Virtual Local Area Network Identifier (VLAN ID) from a 16-bit Tag Control Information (TCI) field.

Valore: `(ca_ntohs(tci) & 0x0FFFU)`

Note:

This constant performs a bitwise AND operation with 0x0FFF to mask out the priority and drop-eligible bits, leaving only the VID. It depends on the ca_ntohs macro for network-to-host byte order conversion. The valid range is 0 to 4095, where 0 is typically reserved for priority-tagged frames and 4095 is reserved for implementation use.

Uso:
Use this when parsing Ethernet frames that contain 802.1Q VLAN tags. Change this only if you need to access the priority bits (PCP) or the Drop Eligible Indicator (DEI) instead of the VID. Warning: Incorrectly modifying the mask will result in corrupted VLAN identification, causing the network stack to drop valid packets or misroute traffic to the wrong virtual network.

`CA_WAIT_FOREVER`

File: `caos/inc/common.h`

Constant representing infinite wait time for caOS kernel operations

Valore: `0xFFFFFFFFU`

Note:
When used as a timeout parameter, CA_WAIT_FOREVER causes threads to wait indefinitely until the requested resource becomes available. This value is a 32-bit unsigned integer set to maximum value (4294967295). It has no dependencies on other flags but requires proper thread management to avoid system deadlocks. Valid range is 0 to 0xFFFFFFFFU, where 0 means no wait and 0xFFFFFFFFU means infinite wait.

Uso:
Use CA_WAIT_FOREVER when you want a thread to block indefinitely until a condition is met, such as waiting for a semaphore, mutex, or message queue. Common in critical sections where timing is not critical. Warning: excessive use can cause system deadlocks if not properly managed, and may prevent proper system shutdown sequences. Avoid using in time-critical applications where timeout behavior is required.

`CA_WDT_TIMEOUT_MIN_MS`

File: `caos/drivers/inc/wdt.h`

Defines the minimum allowed watchdog timeout duration in milliseconds.

Valore: `1U`

Note:
This constant acts as a safety floor for the watchdog timer configuration. If a requested timeout is lower than this value, the driver will enforce this minimum to prevent accidental system resets due to extremely short watchdog windows. It is typically set to 1ms. It is used by the ca_wdt_init function during hardware initialization.

Uso:
Change this value only if your specific hardware or application requirements demand a higher safety margin for the watchdog timer. Increasing this value prevents the system from being configured with a watchdog timeout that is too aggressive, which could lead to spurious resets if the CPU is momentarily busy. Do not set this to 0, as it may cause undefined behavior in the watchdog reload logic.

`CH_CMD`

File: `caos/inc/cli.h`

Enables the command-line interface (CLI) module within the caOS RTOS.

Valore: `0x01U`

Note:
When set to 0x01U, the system initializes the CLI task and command parser. Disabling it (0x00U) removes the CLI functionality, reducing flash memory usage and freeing up CPU cycles. This flag depends on the UART driver being correctly configured in the hardware abstraction layer.

Uso:
Enable this during the development and debugging phase to interact with the system via a serial terminal. Disable it in production builds to save memory and prevent unauthorized access to system commands. Ensure the UART baud rate and buffer sizes are configured correctly before enabling.

`CH_ERASE`

File: `caos/inc/cli.h`

A bitmask flag used by the CLI module to enable the automatic clearing of the terminal screen buffer upon command execution.

Valore: `0x04U`

Note:
When enabled, the system sends ANSI escape sequences to clear the console before printing output. It depends on the terminal emulator supporting standard ANSI codes. The value 0x04U is a bitmask, meaning it can be combined with other CLI configuration flags using the bitwise OR operator.

Uso:
Enable this flag if you want a clean terminal interface for each command response to improve readability. Disable it if you need to maintain a scrollable history of previous command outputs. Ensure your serial terminal software (e.g., PuTTY, Tera Term) is configured to interpret ANSI escape sequences, otherwise, you will see raw characters like '[2J' printed on your screen.

`CH_ESC`

File: `caos/inc/cli.h`

Defines the ASCII character code for the Escape key used to terminate or cancel command-line interface (CLI) operations.

Valore: `0x08U`

Note:
This constant sets the byte value (0x08U, which corresponds to Backspace/Control-H in standard ASCII) that the CLI parser interprets as an interrupt or exit signal. Changing this value requires the terminal emulator sending the commands to be configured to send the same byte. It is a dependency for the CLI input buffer clearing logic.

Uso:

Modify this value only if your specific terminal emulator or serial console uses a different control character for the 'Escape' or 'Cancel' function. Setting this to an incorrect value will cause the CLI to ignore exit commands, potentially leaving the system stuck in an active command state.

`CH_NONE`

File: `caos/inc/cli.h`

Disables the Command Line Interface (CLI) module in the caOS system.

Valore: `0x00U`

Note:
When set to 0x00U, the CLI functionality is active. If set to a non-zero value, the CLI code is excluded from the build, reducing flash memory usage. This flag is independent of the RTOS kernel but may be required by other debug modules.

Uso:
Set this to 0x01U (or any non-zero value) if your final production firmware does not require serial console interaction to save memory. Keep it at 0x00U during development to allow for system monitoring and runtime debugging via the serial port.

`CH_SUBMIT`

File: `caos/inc/cli.h`

A bitmask flag used by the CLI module to enable the submission of commands via the serial interface.

Valore: `0x02U`

Note:
When this bit is set in the CLI configuration register, the system processes incoming character buffers as executable commands. If disabled, the CLI will ignore input strings. It depends on the CLI_ENABLED flag being set to 1. The value 0x02U specifically targets the submission sub-routine within the command parser.

Uso:
Enable this flag when you need to allow users to trigger system functions or configuration changes via the terminal. Disable it in production builds to prevent unauthorized command execution or to save processing cycles if the CLI is only used for monitoring.

`CH_TYPO`

File: `caos/inc/cli.h`

Defines the ASCII character code used by the CLI to represent a detected input error or mistyped command.

Valore: `0x10U /* printable, but no command uses it:  a mistyped`

Note:
This constant sets the internal error character for the command line interface. It must be a valid, printable ASCII value. If set to a value already used by a valid command, the CLI may trigger false error reports. Typical values are in the range 0x00 to 0x7F.

Uso:
Change this value if the default 0x10 conflicts with your specific terminal emulator or if you need to reserve 0x10 for a functional command. Ensure the value is not a control character that could disrupt the serial communication stream.

`CLI_HISTORY_SIZE`

File: `caos/inc/cli.h`

Defines the maximum number of previous commands stored in the CLI buffer for recall.

Valore: `16U`

Note:
This constant determines the depth of the command history stack. Increasing this value consumes more RAM, as each entry occupies a fixed-size buffer. It is independent of the command string length but directly impacts the number of 'up-arrow' key presses supported. Typical values range from 8 to 32 depending on available heap memory.

Uso:
Increase this value if you need to navigate back through a longer sequence of executed commands during debugging. Decrease it if the system is running low on RAM. Ensure the value is a positive integer; setting it to 0 will disable the history feature entirely.

`CLI_PRINTF_N`

File: `caos/inc/cli.h`

A macro wrapper for the Command Line Interface (CLI) that directs formatted output to the system's standard output stream.

Valore: `ca_stdout_printf_n(__VA_ARGS__)`

Note:
This constant maps the CLI_PRINTF_N macro to the internal ca_stdout_printf_n function. Enabling this allows the CLI to send strings to the UART or console buffer. It depends on the underlying hardware abstraction layer (HAL) being initialized for UART/USB-CDC. If this is undefined or points to a null function, CLI commands will produce no visible output.

Uso:
Change this value if you need to redirect CLI output to a different peripheral (e.g., switching from UART1 to UART2) or if you need to implement a custom logging wrapper for debugging. Warning: Ensure the underlying print function is thread-safe, as multiple tasks may attempt to write to the CLI simultaneously, which could lead to garbled text or system crashes if not protected by a mutex.

`CLI_PUT_N`

File: `caos/inc/cli.h`

A macro that defines the output function used by the caOS Command Line Interface to send strings to the serial console.

Valore: `ca_stdout_put_n(MSG)`

Note:

This constant maps the CLI output to a specific hardware abstraction layer function. Enabling or changing this allows the CLI to redirect its output to different peripherals like UART, ITM, or a memory buffer. It depends on the availability of the underlying 'ca_stdout_put_n' function implementation in your board support package.

Uso:
Change this value when porting the CLI to a new hardware target or when you need to redirect debug logs to a different communication interface. Ensure the function assigned is non-blocking or properly synchronized to prevent system hangs during high-frequency CLI output.

`CLI_QUEUE_DEPTH`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/f7xx/f767/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the maximum number of pending command strings the CLI task can buffer before dropping new input.

Valori per MCU:

MCU	Valore
F103	8U
F407	32U
F429	32U
F446	16U
F746	32U
F767	32U
H563	32U
H747	32U
H753	32U

Note:
This constant sets the size of the internal message queue for the Command Line Interface. Increasing this value consumes more RAM (Queue Size * Max Command Length). It is dependent on the available heap memory and the expected burst rate of incoming commands. Typical values range from 8 to 32 depending on the MCU's RAM capacity.

Uso:
Increase this value if you notice 'CLI Buffer Overflow' errors or dropped commands during high-frequency serial communication. Decrease it if the system is running low on RAM. Ensure the value is set according to the specific MCU target to avoid memory exhaustion.

`DEEP_GUARD_MAX`

File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`

File: `hw/f7xx/f746/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the maximum size in bytes for the stack overflow protection guard zone.

Valori per MCU:

MCU	Valore
F407	0x2000U
F429	0x2000U
F446	0x2000U
F746	0x2000U
H747	0x8000U
H753	0x8000U

Note:
This constant sets the memory boundary used by the RTOS to detect stack corruption. Increasing this value provides a larger safety buffer for detecting overflows but consumes more RAM. It is hardware-dependent: F4 series MCUs typically use 0x2000U, while high-performance H7 series require 0x8000U due to larger cache and memory alignment requirements.

Uso:
Adjust this value if you encounter HardFaults related to stack overflows or if the system reports memory corruption in task stacks. Do not decrease this value below the manufacturer-recommended default for your specific MCU, as it will disable the RTOS's ability to detect stack violations, potentially leading to silent system crashes.

`DHCP_BIND_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits for a DHCP server to assign an IP address.

Valore: `60000U`

Note:
When enabled, the network stack will attempt to acquire an IP for this duration before timing out. If set too low, the device may fail to connect on slow networks. If set too high, the system boot time increases significantly during network failures. Typical values range from 5000 to 60000.

Uso:
Increase this value if the device frequently fails to obtain an IP address in environments with high network latency or slow DHCP servers. Decrease it if you need the device to fall back to a static IP or error state faster during startup.

`DHCP_CLIENT_PORT`

File: `caos/net/inc/net_proto.h`

Defines the UDP port number used by the caOS DHCP client to listen for server responses.

Valore: `68U`

Note:

This constant sets the destination port for DHCP discovery and request packets. It must be set to 68U to comply with the standard DHCP protocol (RFC 2131). Changing this value will prevent the device from communicating with standard DHCP servers, as they are hardcoded to send replies to port 68.

Uso:
This value should generally remain at 68U. Change this only if you are implementing a custom DHCP server or a specialized network simulation environment where the server is configured to listen and respond on a non-standard port.

`DHCP_DISCOVER_RETRY_N`

File: `os_config.h`

Defines the maximum number of DHCP DISCOVER packet retransmission attempts before the network stack reports a failure.

Valore: `3U`

Note:
When enabled, the system will attempt to request an IP address from a DHCP server up to this count. If the server does not respond within the timeout period, the stack stops trying. Increasing this value improves reliability on unstable networks but increases the total time taken to detect a network failure. Typical values range from 3 to 10.

Uso:
Increase this value if your device frequently fails to obtain an IP address in environments with high packet loss or slow DHCP servers. Decrease it if you need the system to fail fast and proceed to a fallback static IP configuration or error state more quickly.

`DHCP_MSG_ACK`

File: `caos/net/inc/net_proto.h`

Defines the numeric identifier for the DHCP Acknowledge (DHCPACK) message type.

Valore: `5U`

Note:
This constant represents the specific opcode used in the DHCP protocol to confirm a client's request for an IP address. It is used by the network stack to filter incoming UDP packets. It must remain set to 5U to comply with the standard DHCP protocol (RFC 2131). Changing this value will cause the network stack to fail to recognize server acknowledgments, resulting in failed IP address assignment.

Uso:
Do not modify this value under normal circumstances. It should only be changed if you are implementing a custom, non-standard DHCP-like protocol or if the network stack is being ported to a system that uses a proprietary message mapping. Incorrect values will prevent the device from completing the network handshake.

`DHCP_MSG_DISCOVER`

File: `caos/net/inc/net_proto.h`

Defines the message type identifier for a DHCP Discover packet used during the initial network address acquisition phase.

Valore: `1U`

Note:
This constant represents the specific opcode (1) sent by the client to broadcast a request for available DHCP servers. It is a fixed protocol value defined by RFC 2131. Changing this value will cause the DHCP server to ignore the client's discovery requests, effectively breaking the network initialization process.

Uso:
This value should never be changed during standard application development. It is used internally by the caOS network stack to construct outgoing DHCP packets. If you are debugging network traffic with a packet sniffer like Wireshark, use this constant to verify that the client is correctly identifying its broadcast messages as 'Discover' packets.

`DHCP_MSG_NAK`

File: `caos/net/inc/net_proto.h`

Defines the DHCP Negative Acknowledgment (NAK) message type identifier used in network communication.

Valore: `6U`

Note:
This constant represents the specific numeric code (6) sent by a DHCP server to inform a client that its requested IP address is invalid or no longer available. It is a protocol-level identifier required for the DHCP state machine to correctly parse incoming UDP packets. It has no configurable range as it is a fixed protocol constant defined by RFC 2131.

Uso:
Do not modify this value unless you are implementing a custom or non-standard DHCP protocol extension. Changing this will cause the caOS network stack to fail to recognize NAK messages from standard DHCP servers, potentially leading to infinite loops or connection timeouts during the IP address acquisition phase.

`DHCP_MSG_OFFER`

File: `caos/net/inc/net_proto.h`

Defines the numeric identifier for a DHCP Offer message type within the network stack.

Valore: `2U`

Note:
This constant represents the specific message type field in a DHCP packet header. It is used by the network parser to distinguish an 'Offer' from other DHCP messages like 'Discover' or 'Request'. It must match the standard DHCP protocol specification (RFC 2131) and should not be modified unless the underlying network stack implementation is being ported to a non-standard protocol.

Uso:
This value is used internally by the caOS network driver to process incoming DHCP packets. You should never change this value during standard application development. Modifying this constant will cause the device to fail to negotiate an IP address with DHCP servers, effectively breaking network connectivity.

`DHCP_MSG_REQUEST`

File: `caos/net/inc/net_proto.h`

Defines the DHCP Request message type identifier used in the network stack.

Valore: `3U`

Note:
This constant represents the numeric code (3) sent in the DHCP message type option field. It is a fixed protocol value defined by RFC 2131. Changing this value will cause the DHCP server to ignore or reject the client's request, effectively breaking the IP address assignment process.

Uso:
This value should never be changed by the developer. It is used internally by the caOS network stack to identify and construct DHCP Request packets. If you are debugging network traffic with a packet sniffer like Wireshark, you can use this constant to verify that the device is correctly identifying its own outgoing request packets.

`DHCP_OFFER_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits to receive a DHCP offer from a server.

Valore: `4000U`

Note:
This constant sets the duration of the blocking wait state during the network initialization phase. If the DHCP server does not respond within this window, the request will time out. It depends on the network stack initialization sequence and should be set higher than the typical round-trip time of your local network infrastructure. Valid range is typically 1000U to 10000U.

Uso:
Increase this value if your device is failing to obtain an IP address on slow or congested networks. Decrease it if you need the system to fail fast and proceed to a fallback static IP configuration or error state more quickly. Setting this value too low may cause intermittent connection failures in environments with high network latency.

`DHCP_RENEW_TIMEOUT_MS`

File: `os_config.h`

Defines the duration in milliseconds the system waits for a DHCP server response before attempting a renewal retry.

Valore: `10000U`

Note:

This constant directly impacts the network stack's responsiveness during IP lease renewal. If set too low, the system may trigger unnecessary retries on slow networks; if set too high, it delays recovery from network interruptions. It depends on the underlying network driver's ability to handle asynchronous timeouts. Typical values range from 5000U to 30000U depending on network latency requirements.

Uso:
Increase this value if the device frequently loses its IP address on congested or high-latency networks. Decrease it only if the application requires faster detection of DHCP server failures. Ensure the value is not set lower than the round-trip time of your network infrastructure to avoid constant, failed renewal loops.

`DHCP_REQUEST_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits for a DHCP server to respond to a request.

Valore: `4000U`

Note:
This constant sets the duration of the blocking wait state during the network initialization phase. If the DHCP server does not respond within this window, the request is considered failed. It depends on the underlying network stack's timer resolution. Typical values range from 2000 to 10000 depending on network latency and reliability.

Uso:
Increase this value if the device fails to obtain an IP address on slow or congested networks. Decrease it if you need the system to fail fast and proceed to a fallback static IP configuration or error state. Setting this too low may cause intermittent connection failures in high-traffic environments.

`DHCP_RETRY_BACKOFF_MS`

File: `os_config.h`

Defines the time interval in milliseconds to wait before retrying a failed DHCP request.

Valore: `5000U`

Note:
This constant controls the delay between consecutive DHCP discovery attempts. Increasing this value reduces network traffic and power consumption during network outages, while decreasing it speeds up reconnection times. It is dependent on the network stack initialization and typically ranges from 1000U to 10000U.

Uso:
Adjust this value if your device takes too long to reconnect after a network drop or if the DHCP server is overloaded. Use a higher value if you are operating on a battery-powered device to minimize radio activity, or a lower value if rapid network availability is critical for your application.

`DHCP_SERVER_PORT`

File: `caos/net/inc/net_proto.h`

Defines the UDP port number used by the caOS DHCP server to listen for client requests.

Valore: `67U`

Note:
This constant sets the destination port for incoming DHCP discovery and request packets. It must be set to 67U to comply with the standard DHCP protocol (RFC 2131). Changing this value will prevent standard DHCP clients from discovering the server, as they are hardcoded to send requests to port 67.

Uso:
Keep this value at 67U for standard network operations. Only change this if you are implementing a custom, non-standard DHCP-like protocol or if you are running a secondary DHCP server instance on a non-standard port for testing purposes. Incorrect values will result in the server failing to receive any client configuration requests.

`DHCP_TASK_STACK_MIN`

File: `caos/net/inc/dhcp_service.h`

Defines the minimum stack size in bytes allocated for the DHCP client background task.

Valore: `2048U`

Note:
This value sets the memory footprint for the DHCP task. If set too low, the system will trigger a stack overflow exception during network negotiation. It depends on the underlying network stack's buffer requirements and the complexity of the DHCP options being processed. Typical values range from 1024 to 4096 bytes depending on the RTOS heap configuration.

Uso:
Increase this value if the system crashes or exhibits undefined behavior specifically when the device attempts to acquire an IP address. Decrease it only if you are extremely constrained by RAM and have verified via stack watermarking that the task uses significantly less than 2048 bytes.

`DMA_CH_INVALID`

File: `caos/drivers/inc/dma.h`

A sentinel value representing an uninitialized or invalid DMA channel handle.

Valore: `((ca_dma_ch_t){0xFFU, 0xFFU})`

Note:
This constant acts as a null-pointer equivalent for DMA channel structures. It is used to initialize variables before a valid channel is assigned. It has no functional impact on hardware but is critical for logic checks in driver functions. It is a constant structure of type ca_dma_ch_t with both stream and channel fields set to 0xFF.

Uso:
Use this value to initialize DMA channel variables or to reset a channel handle after a transfer is completed or aborted. Always compare your DMA channel variables against this constant

before attempting to start a transfer to prevent accessing invalid hardware registers. Never attempt to pass this value directly to hardware configuration functions, as it will trigger an error or undefined behavior.

`DMA_MAX_CHANNELS`

File: `caos/drivers/inc/dma.h`

Defines the total number of available DMA channels supported by the hardware abstraction layer.

Valore: `24U`

Note:
This constant sets the upper bound for the DMA channel array size in the driver. If set higher than the physical hardware capability, it may lead to out-of-bounds memory access or invalid register addressing. If set lower, additional DMA channels provided by the STM32 silicon will remain inaccessible to the RTOS.

Uso:
Adjust this value only when porting the caOS driver to a different STM32 microcontroller series with a different number of DMA streams or channels. Ensure the value matches the specific datasheet for your MCU. Incorrect values will cause silent failures or hard faults when attempting to initialize or trigger DMA transfers on higher-indexed channels.

`DMA_REQ_NONE`

File: `caos/drivers/inc/dma.h`

A sentinel value representing the absence of a DMA request channel assignment.

Valore: `0xFFFFU`

Note:
When set to 0xFFFFU, the driver interprets this as 'no DMA channel requested'. It is used as a default value in peripheral configuration structures to prevent accidental activation of DMA streams. It has no dependencies on other flags but must be checked by initialization functions to skip DMA setup logic.

Uso:
Use this value when initializing a peripheral structure that supports DMA but does not require it for the current application. Do not use this value if you intend to perform data transfers, as it will cause the driver to ignore the DMA configuration and potentially fall back to polling mode or return an error.

`DNS_CLASS_IN`

File: `caos/net/inc/net_proto.h`

Defines the Internet (IN) class identifier for DNS queries as specified in RFC 1035.

Valore: `1U`

Note:
This constant represents the standard class value for IP-based networks. It is used in the DNS header structure to indicate that the query pertains to the Internet protocol family. It is a fixed

protocol constant and should not be modified, as changing it will cause DNS servers to reject requests as malformed or unsupported.

Uso:
Use this constant when manually constructing DNS packets or filtering incoming DNS traffic. Do not change this value unless you are implementing a non-standard network protocol that specifically requires a different DNS class identifier.

`DNS_FLAGS_QR`

File: `caos/net/inc/net_proto.h`

A bitmask flag used to identify if a DNS packet is a Query (0) or a Response (1).

Valore: `0x8000U`

Note:
When this bit is set (0x8000), the DNS header indicates the packet is a response from a server. When cleared, it indicates a client query. This flag is typically used in conjunction with bitwise AND operations to parse incoming network buffers. It is a standard field defined by RFC 1035 and must not be modified.

Uso:
Do not change this value as it is defined by the DNS protocol specification. Use this constant when writing custom packet parsers or debugging network traffic to verify if a received packet is a valid response to a previous request.

`DNS_FLAGS_RCODE`

File: `caos/net/inc/net_proto.h`

A bitmask used to extract the 4-bit Response Code (RCODE) field from a DNS message header.

Valore: `0x000FU`

Note:
This constant represents the mask 0x000F, which isolates the lower 4 bits of the DNS flags field. It is used to identify the status of a DNS query (e.g., No Error, Format Error, Server Failure). It depends on the DNS header structure defined in the network stack and is typically used in conjunction with bitwise AND operations on the flags field.

Uso:
Use this when parsing incoming DNS responses to determine if the server successfully resolved the domain or returned an error. Do not modify this value unless the underlying DNS protocol implementation changes, as it is strictly defined by RFC 1035. Incorrect values will result in the system misinterpreting DNS server error codes.

`DNS_FLAGS_RD`

File: `caos/net/inc/net_proto.h`

The Recursion Desired (RD) flag bit for DNS query headers.

Valore: `0x0100U`

Note:
When set to 0x0100U, this bit instructs the DNS server to perform a recursive search if it does not have the requested record in its cache. If disabled (0x0000U), the server will only return what it already knows or provide a referral to another server. This flag is typically ORed with other header flags to construct the full DNS request packet.

Uso:
Enable this flag when your device needs to resolve domain names through a standard recursive DNS server (like those provided by ISPs or public DNS providers). Disable it only if you are communicating with an authoritative-only server or if you want to minimize network traffic by preventing the server from performing additional lookups on your behalf.

`DNS_PENDING_MAX`

File: `os_config.h`

Defines the maximum number of concurrent DNS resolution requests allowed in the system queue.

Valore: `4U`

Note:
This constant determines the size of the internal buffer for pending DNS queries. Increasing this value allows more simultaneous lookups but consumes more RAM in the system heap. It is dependent on the network stack being initialized and typically ranges from 1 to 16 depending on available memory.

Uso:
Increase this value if your application frequently experiences 'DNS_QUEUE_FULL' errors when performing multiple network requests simultaneously. Decrease it if the system is running low on memory. Setting this value too high may lead to heap exhaustion during peak network activity.

`DNS_PORT`

File: `caos/net/inc/net_proto.h`

Defines the standard UDP port number used for Domain Name System (DNS) queries.

Valore: `53U`

Note:
This constant sets the destination port for outgoing DNS requests. It is a 16-bit unsigned integer. Changing this value will prevent the device from resolving hostnames unless the remote DNS server is also configured to listen on the new port. It is a dependency for the caOS network stack's resolver module.

Uso:
Change this value only if you are operating within a non-standard network environment or a private network that uses a custom DNS port. Do not change this for standard internet connectivity, as 53 is the globally recognized IANA standard for DNS.

DNS_RCODE_NXDOMAIN

File: caos/net/inc/net_proto.h

A DNS response code indicating that the domain name requested does not exist.

Valore: 3U

Note:
This constant represents the numeric value 3, which is returned by a DNS server when a query fails because the requested hostname cannot be resolved. It is used within the network stack's DNS client module to interpret server responses. It has no configurable range as it is a fixed protocol-defined constant.

Uso:
Use this constant when writing conditional logic to handle DNS lookup failures. Compare the result of your DNS query function against this flag to distinguish between a network timeout and a legitimate 'domain not found' error. Do not modify this value, as it must strictly adhere to the DNS protocol specification (RFC 1035).

DNS_RCODE_OK

File: caos/net/inc/net_proto.h

Represents the success status code for a DNS query response.

Valore: 0U

Note:
This constant is defined as 0U, which is the standard value for 'No Error' in the DNS protocol header. It is used by the caOS network stack to validate incoming DNS packets. If a received packet's RCODE field matches this constant, the system proceeds with parsing the resource records; otherwise, it triggers an error handling routine.

Uso:
This value should not be changed as it is defined by the RFC 1035 standard. It is primarily used in conditional checks when processing network responses. If your application is receiving unexpected DNS errors, check this constant against the RCODE field in the received packet header to debug network configuration or server-side issues.

DNS_RESPONSE_TIMEOUT_MS

File: os_config.h

Defines the maximum time in milliseconds the system waits for a DNS server to respond to a hostname resolution request.

Valore: 3000U

Note:
When enabled, the network stack will block or pend the calling task for up to this duration. If no response is received within this window, the DNS query fails. This value is dependent on the network stack's tick rate and should be set higher than the expected round-trip time of your network environment. Typical values range from 1000ms to 5000ms.

Uso:

Increase this value if your device is operating on high-latency networks (e.g., cellular or congested Wi-Fi) to prevent premature timeouts. Decrease it if you need the application to fail fast and recover quickly when the network is unreachable. Setting this value too low may cause frequent DNS resolution failures, while setting it too high may cause the application to hang unnecessarily during network outages.

DNS_RETRY_N

File: os_config.h

Defines the maximum number of times the DNS client will attempt to resolve a hostname before returning an error.

Valore: 2U

Note:
This constant controls the retry logic in the network stack. Increasing this value allows for more attempts in unstable network environments but increases the total blocking time for the calling task. It depends on the underlying network driver's timeout settings. Typical values range from 1 to 5.

Uso:
Increase this value if your device frequently fails to resolve hostnames due to high packet loss or slow network response times. Decrease it if you need to fail fast to maintain system responsiveness. Setting this too high may cause task starvation or watchdog timeouts if the network is completely unreachable.

DNS_TYPE_A

File: caos/net/inc/net_proto.h

Defines the protocol identifier for IPv4 address resolution requests in the caOS networking stack.

Valore: 1U

Note:
This constant represents the 'A' record type in DNS queries. It is a mandatory value for the DNS client module to resolve hostnames into 32-bit IPv4 addresses. It must be set to 1U to comply with RFC 1035 standards. Changing this value will cause the DNS resolver to request incorrect record types, leading to resolution failures.

Uso:
Use this constant when calling the DNS query function to specify that you are looking for an IPv4 address. Do not modify this value unless you are intentionally implementing a different DNS record type (e.g., AAAA for IPv6 or MX for mail servers) and the underlying network stack supports it.

DUMP_BUFFER_SIZE

File: hw/f4xx/f407/objmap.h
File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h

File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the fixed size in bytes of the internal memory buffer used for system diagnostic dumps and error logging.

Valori per MCU:

MCU	Valore
F407	128
F429	128
F446	128
F746	128
H563	128
H747	128
H753	128

Note:
This constant allocates a static memory block for capturing system state information during a crash or debug event. Increasing this value allows for more detailed log entries but consumes more RAM. It is currently set to 128 bytes across all supported STM32 platforms (F4, F7, H5, H7) to ensure consistent diagnostic output capacity regardless of the specific MCU architecture.

Uso:
Modify this value if you need to capture larger diagnostic payloads or if you are running out of RAM and need to reclaim space. If set too small, diagnostic logs may be truncated, leading to incomplete information during debugging. Ensure the value is a multiple of the word size (4 bytes) for optimal memory alignment on ARM Cortex-M cores.

`DUMP_TASK_ADDR`

File: `caos/inc/scheduler.h`

Enables the inclusion of task entry point addresses in the system dump logs for debugging purposes.

Valore: `0x02`

Note:
When enabled (0x02), the scheduler appends the memory address of each task's function to the diagnostic output. This flag depends on the system's logging subsystem being initialized. It is typically used in conjunction with other diagnostic flags and consumes a small amount of additional memory in the dump buffer.

Uso:
Enable this flag when you need to identify which specific task function is associated with a stack overflow or a task crash during post-mortem analysis. Do not enable this in production builds if memory constraints are extremely tight, as it increases the size of the diagnostic log entries.

`DUMP_TASK_ALL`

File: `caos/inc/scheduler.h`

A bitmask flag used to enable the logging or diagnostic dumping of all active task control blocks (TCBs) within the scheduler.

Valore: `0xFF`

Note:
When enabled, the system will iterate through all registered tasks and output their current state, stack usage, and priority to the debug interface. This flag depends on the system's debug UART or ITM port being initialized. It is typically used as a bitwise mask; setting it to 0xFF ensures all task-related diagnostic modules are active. Disabling it reduces CPU overhead and memory footprint during runtime.

Uso:
Change this value when you need to perform a system-wide health check or debug a task-related crash. Use it during the development and integration phase to monitor task starvation or stack overflows. Warning: Enabling this in production code can significantly degrade real-time performance and increase interrupt latency due to the high volume of serial data transmission.

`DUMP_TASK_HDR`

File: `caos/inc/scheduler.h`

Enables or disables the inclusion of task control block headers in system memory dumps.

Valore: `0x01`

Note:
When set to 0x01, the scheduler appends task metadata (such as stack pointers and state) to crash dumps. Disabling this (0x00) reduces the size of the dump file but makes debugging task-related crashes significantly harder. It depends on the system's logging or debug interface being initialized.

Uso:
Enable this flag during the development and testing phases to facilitate post-mortem debugging of task stack overflows or deadlocks. Disable it in production builds if memory constraints are extremely tight or if you need to minimize the footprint of diagnostic data.

`DUMP_TASK_REG`

File: `caos/inc/scheduler.h`

Enables the inclusion of CPU register snapshots in task dump reports during system crashes.

Valore: `0x04`

Note:
When enabled (non-zero), the scheduler saves the current CPU register state to the task control block upon a fault. This flag requires sufficient stack space to store the register context. It is typically used in conjunction with a debugger or a serial logging utility to perform post-mortem analysis.

Uso:
Enable this flag during the development and debugging phase to identify the exact instruction pointer and register values at the moment of a task crash. Disable it in production builds to save RAM and reduce the overhead of context switching and exception handling.

`DUMP_TASK_STACK`

File: `caos/inc/scheduler.h`

Enables the automatic dumping of task stack memory contents to the debug console upon a task crash or stack overflow event.

Valore: `0x08`

Note:
When enabled (0x08), the kernel triggers a memory dump of the task's stack area to the UART/ITM interface during a fault. This flag depends on the system having a configured debug output stream. Typical values are 0x00 (disabled) or 0x08 (enabled). Enabling this increases the size of the fault handler code and may slightly increase the time spent in the error recovery routine.

Uso:
Enable this flag during the development and debugging phase to identify the root cause of stack overflows or memory corruption. Disable it in production builds to reduce binary size and prevent sensitive data from being printed to the debug interface.

`DUMP_TASK_STATS`

File: `caos/inc/scheduler.h`

Enables the collection and reporting of CPU usage and stack depth statistics for individual tasks.

Valore: `0x10`

Note:
When enabled (0x10), the scheduler tracks execution time and stack high-water marks for each task. This increases memory overhead per task control block (TCB) and adds a small CPU cycle penalty to context switches. It requires the system heap to be initialized and is typically used in conjunction with a debug console or telemetry module.

Uso:
Enable this flag during the development and profiling phase to identify tasks that are starving the CPU or nearing stack overflow. Disable it in production builds to save RAM and improve real-time performance. Ensure that your task stack sizes are large enough to accommodate the extra overhead if this flag is enabled.

`ECDSA_P256_HASH_SIZE`

File: `caos/crypto/inc/ecdsa_p256.h`

Defines the fixed byte length of the hash used in ECDSA P-256 signature operations.

Valore: `32`

Note:
This constant is set to 32 bytes, which corresponds to the 256-bit output size of the SHA-256 algorithm. It is a hard requirement for the ca_ecdsa_p256_sign_hash and ca_ecdsa_p256_verify_hash functions. Changing this value will cause cryptographic mismatches and likely lead to runtime errors or failed signature verifications.

Uso:

Do not modify this value. It is fixed by the ECDSA P-256 standard (FIPS 186-4). If you are implementing a custom signing flow, ensure your input buffer matches this size exactly before calling ca_ecdsa_p256_sign_hash.

ECDSA_P256_PRIVATE_SIZE

File: `caos/crypto/inc/ecdsa_p256.h`

Defines the fixed byte length of a P-256 elliptic curve private key.

Valore: `32`

Note:
This constant is set to 32 bytes, which corresponds to 256 bits. It is a fundamental requirement for the ca_ecdsa_p256_* family of functions. Changing this value will cause buffer overflows or cryptographic failures in any function expecting a standard NIST P-256 key, as the underlying math relies on this specific size.

Uso:
This value should not be changed. It is used to allocate memory buffers for private keys when calling ca_ecdsa_p256_keygen or when passing private keys to signing functions. If you are handling raw key data, use this constant to ensure your buffers are correctly sized: uint8_t my_key[ECDSA_P256_PRIVATE_SIZE];

ECDSA_P256_PUBLIC_SIZE

File: `caos/crypto/inc/ecdsa_p256.h`

Defines the fixed byte length of an ECDSA P-256 public key in the caOS crypto stack.

Valore: `64`

Note:
This constant is set to 64 bytes, representing the concatenation of the X and Y coordinates (32 bytes each) of the elliptic curve point. It is used by ca_ecdsa_p256_verify and related functions to validate buffer sizes. Changing this value will cause buffer overflows or validation failures in the cryptographic subsystem, as the underlying hardware/software implementation expects exactly 64 bytes for uncompressed P-256 public keys.

Uso:
Do not change this value. It is a protocol-defined constant for the NIST P-256 curve. If you are handling public keys, ensure your buffers are allocated with this size using ca_memory_allocate(ECDSA_P256_ to prevent memory corruption.

ECDSA_P256_SIGNATURE_SIZE

File: `caos/crypto/inc/ecdsa_p256.h`

Defines the fixed byte length of an ECDSA P-256 digital signature.

Valore: `64`

Note:
The value 64 represents the concatenation of two 32-byte integers (r and s) that constitute a standard ECDSA signature on the P-256 curve. This constant is used for buffer allocation and

validation checks in cryptographic operations. It is a fixed protocol requirement and should not be modified.

Uso:
Use this constant when allocating buffers for signature storage or when passing length arguments to functions like ca_ecdsa_p256_sign or ca_ecdsa_p256_verify. Do not change this value, as it is mathematically tied to the P-256 curve specification; changing it will cause cryptographic failures.

`ED25519_PUBLIC_SIZE`

File: `caos/crypto/inc/ed25519.h`

Defines the fixed byte length of an Ed25519 public key in the caOS cryptographic library.

Valore: `32`

Note:
This constant is set to 32 bytes, which is the standard size for Ed25519 public keys as per RFC 8032. Changing this value will cause buffer overflows or cryptographic verification failures in any function expecting a standard Ed25519 key. It is a hard-coded dependency for all signing and verification routines within the caOS crypto stack.

Uso:
Do not modify this value unless you are implementing a non-standard variant of the Ed25519 algorithm. It is used to allocate memory for key storage and to define the bounds for array copies. If you encounter 'invalid key size' errors, ensure your input buffer matches this constant exactly.

`ED25519_SEED_SIZE`

File: `caos/crypto/inc/ed25519.h`

Defines the fixed byte length of the seed used for generating Ed25519 cryptographic keys.

Valore: `32`

Note:
This constant is set to 32 bytes (256 bits), which is the standard requirement for the Ed25519 algorithm. Changing this value will cause cryptographic functions to fail or produce invalid keys, as the underlying library expects exactly 32 bytes of entropy. It has no dependencies on other RTOS flags but is critical for all secure communication modules.

Uso:
Do not change this value under normal circumstances. It should only be modified if you are implementing a custom cryptographic wrapper that requires a different input size, though this is highly discouraged as it breaks compatibility with standard Ed25519 implementations. Ensure any buffer allocated for the seed is exactly this size to prevent memory overflows.

`ED25519_SIGNATURE_SIZE`

File: `caos/crypto/inc/ed25519.h`

Defines the fixed byte length of an Ed25519 digital signature.

Valore: `64`

Note:
This constant is set to 64 bytes, which is the standard size for Ed25519 signatures as per RFC 8032. Changing this value will cause cryptographic verification functions to fail or trigger buffer overflows if the underlying memory buffers are not resized accordingly. It is a hard-coded requirement for the Ed25519 algorithm implementation in caOS.

Uso:
Do not modify this value unless you are porting a non-standard variant of the Ed25519 algorithm. It is used to allocate stack or heap memory for signature storage. Ensure that any buffers passed to signing or verification functions are at least this size to prevent memory corruption.

`ENABLE_CLI`

File: `os_config.h`

Enables the Command Line Interface (CLI) module for real-time system debugging and interaction via UART.

Valore: `1`

Note:
When set to 1, the system initializes the CLI task and allocates memory for command buffers. Disabling it (0) reduces flash memory usage and frees up CPU cycles. This flag depends on the UART driver being initialized in the hardware abstraction layer.

Uso:
Enable this during development to inspect task states, memory usage, and system variables in real-time. Disable it in production builds to save memory and prevent unauthorized access to system commands.

`ENABLE_CLI_STDOUT`

File: `caos/inc/cli.h`

Enables or disables the redirection of the Command Line Interface (CLI) output to the standard output (STDOUT) stream.

Valore: `1`

Note:
When set to 1, all CLI responses are routed to the system's default serial output (usually UART). If set to 0, the CLI will not print any feedback to the console. This flag depends on the hardware abstraction layer (HAL) being initialized for UART communication. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this during development to debug system commands and view task status via a serial terminal. Disable it in production builds to reduce CPU overhead and prevent sensitive system information from being exposed through the serial port.

`ENABLE_DBG_UART`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`

File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Enables the dedicated debug UART peripheral for system logging and RTOS kernel diagnostics.

Valori per MCU:

MCU	Valore
F103	1
F407	1
F429	1
F446	1
F746	1
H563	1
H747	1
H753	1

Note:
When enabled, the RTOS redirects kernel trace messages and system assertions to the hardware UART port. Disabling this flag saves CPU cycles and reduces power consumption by stopping the UART peripheral and associated DMA/interrupt overhead. It requires the corresponding UART pins to be physically connected to a serial-to-USB adapter on your development board.

Uso:
Enable this during the development and debugging phase to monitor system health and catch runtime errors via a serial terminal. Disable this flag in production builds to minimize binary size and prevent potential security leaks of internal system states through the debug port.

`ENABLE_ITM`

File: `os_config.h`

Enables or disables the Instrumentation Trace Macrocell (ITM) for real-time debugging output.

Valore: `0`

Note:
When set to 1, the RTOS redirects system logs and trace data to the ITM port, allowing high-speed debugging via an SWO pin. When set to 0, this feature is disabled, saving CPU cycles and memory. This flag requires the hardware debugger to support SWO tracing and the corresponding pin to be configured in the MCU.

Uso:
Enable this (set to 1) when you need to monitor task switching or system events in real-time without stopping the CPU. Disable it (set to 0) for production builds to reduce code size and prevent potential timing issues caused by trace overhead. Ensure your debugger is connected to the SWO pin before enabling.

`ENABLE_SENSOR`

File: `os_config.h`

Global master switch to enable or disable the sensor driver subsystem within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel initializes sensor-related tasks and hardware abstraction layers. When set to 0, all sensor-related code is excluded from the build, reducing flash memory usage. This flag is a prerequisite for other sensor-specific configurations like SENSOR_POLLING_RATE and SENSOR_I2C_ADDRESS.

Uso:
Set to 1 during standard development to enable sensor data acquisition. Set to 0 if your specific hardware variant does not include sensors or if you need to free up memory space. Ensure this is enabled before attempting to call any sensor API functions, otherwise, the linker will report undefined references.

`ENABLE_STDOUT`

File: `os_config.h`

Enables or disables the redirection of standard output (printf) to the UART peripheral.

Valore: `1`

Note:
When set to 1, the RTOS initializes the hardware UART and routes stdout to it. When set to 0, all printf calls are ignored or redirected to a null device. This flag depends on the UART_PORT_CONFIG being defined in the hardware abstraction layer. Typical values are 0 (production) or 1 (debugging).

Uso:
Enable this during development to view system logs and debug messages via a serial terminal. Disable it before deploying to production to save CPU cycles, reduce power consumption, and prevent potential blocking issues if the UART buffer becomes full.

`ENABLE_UART`

File: `os_config.h`

Enables or disables the hardware abstraction layer for UART communication within the RTOS.

Valore: `0`

Note:
When set to 1, the RTOS initializes UART peripherals and includes driver code in the build. When set to 0, all UART-related functions are excluded, reducing the binary footprint. This flag must be enabled if your application uses serial debugging, logging, or external UART-based sensors.

Uso:

Set to 1 if your project requires serial communication or console logging. Set to 0 to save flash memory and RAM if UART is not used. Warning: disabling this will cause compilation errors if your application code calls any UART-related API functions.

EN_ADC

File: os_config.h

Enables the Analog-to-Digital Converter (ADC) driver subsystem within the caOS RTOS.

Valore: 1

Note:
When set to 1, the kernel initializes ADC hardware abstraction layers and allocates necessary memory for ADC peripheral management. If set to 0, all ADC-related API calls will return an error code or trigger a hard fault. This flag depends on the hardware abstraction layer (HAL) being correctly configured in the STM32CubeMX project settings.

Uso:
Set this to 1 when your application requires reading analog sensors or voltage levels. Disable it (set to 0) to save flash memory and RAM if your project does not use any ADC channels. Ensure that the corresponding ADC clock is enabled in the system clock configuration before enabling this flag.

EN_AES

File: os_config.h

Enables hardware-accelerated AES encryption support within the caOS kernel and middleware.

Valore: 1

Note:
When set to 1, the system initializes the STM32 hardware cryptographic peripheral and links the AES driver to the OS task scheduler. Disabling this (0) reduces the binary footprint and saves RAM by excluding the crypto-library stack. This flag depends on the target MCU having a hardware AES engine; if enabled on a device without one, the system will trigger a hard fault during initialization.

Uso:
Enable this flag when your application requires secure data transmission (e.g., TLS, encrypted storage, or secure boot). Change this to 0 if your project does not use encryption to optimize memory usage. Warning: Ensure the STM32 model supports hardware AES before setting this to 1, otherwise the kernel will fail to boot.

EN_AES_CHANNEL_SERVICE

File: os_config.h

Enables the hardware-accelerated AES encryption service within the caOS kernel.

Valore: 1

Note:

When set to 1, the RTOS initializes the STM32 hardware cryptographic peripheral and exposes the AES API for task-level encryption. Disabling this (0) reduces the kernel memory footprint and removes the dependency on the hardware crypto driver. This flag requires the STM32 hardware to have a built-in AES peripheral. The AES channel service also enables secure key management and hardware-accelerated cryptographic operations that significantly improve performance compared to software implementations.

Uso:
Enable this when your application requires secure data transmission or storage (e.g., TLS, encrypted logging, secure boot). Change this to 0 if you are running on a low-power device without crypto hardware or if you need to save flash memory space. Ensure that the corresponding hardware clock is enabled in the system initialization if this flag is set to 1. Warning: Setting this to 1 on devices without AES hardware will cause kernel initialization failure. Typical use cases include IoT devices requiring secure communication, embedded systems with security requirements, and applications handling sensitive data where performance is critical.

`EN_AES_GCM_SW_TEST`

File: `os_config.h`

Enables the software-based implementation of the AES-GCM cryptographic algorithm for testing purposes.

Valore: `1`

Note:
When set to 1, the system includes the software library for AES-GCM encryption and decryption. If set to 0, the software implementation is excluded to save flash memory. This flag is independent of hardware-accelerated AES modules but may conflict if hardware drivers are improperly initialized. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag during the development and validation phase to verify cryptographic logic without relying on specific STM32 hardware peripherals. Disable it in production builds to reduce binary size and memory footprint, especially if hardware acceleration is available or if AES-GCM is not required by the application.

`EN_ARP_SERVICE`

File: `os_config.h`

Enables or disables the Address Resolution Protocol (ARP) service within the caOS network stack.

Valore: `1`

Note:
When set to 1, the RTOS handles ARP requests and responses to map IP addresses to MAC addresses. Disabling this (0) will prevent the device from communicating over Ethernet unless static ARP entries are manually managed. This flag depends on the underlying Ethernet driver being initialized and the TCP/IP stack being active.

Uso:

Enable this (1) for standard network communication where the device needs to discover or respond to other nodes on the local network. Disable it (0) only in highly specialized, static-network environments where you want to minimize memory footprint or prevent the device from responding to network discovery traffic.

`EN_BARRIER`

File: `os_config.h`

Enables or disables the synchronization barrier primitive within the caOS RTOS kernel.

Valore: `1`

Note:
When set to 1, the kernel includes code for barrier objects, allowing multiple tasks to wait until a specified number of threads have reached a synchronization point. Disabling this (0) reduces the total flash memory footprint by removing the barrier management logic. This flag has no direct dependencies on other kernel objects but is required if your application uses barrier-based task coordination.

Uso:
Enable this flag if your application architecture requires multiple tasks to synchronize at a specific execution gate before proceeding. You should disable it if your project is memory-constrained and does not utilize barriers to save code space. Ensure that all tasks intended to use barriers are initialized correctly after enabling this flag to avoid null pointer dereferences.

`EN_BIG_E`

File: `os_config.h`

Configures the system to use Big-Endian byte order for data storage and memory access.

Valore: `1`

Note:
When enabled (1), the system stores the most significant byte at the lowest memory address. When disabled (0), it defaults to Little-Endian. This flag must match the hardware architecture and the endianness of any external communication protocols (like network packets or specific sensors) to prevent data corruption.

Uso:
Change this value only if your specific STM32 hardware configuration or external peripheral communication requires Big-Endian format. Incorrectly setting this flag will cause multi-byte variables (like uint32_t) to be read or written in reverse, leading to critical logic errors and system instability.

`EN_BLOCK_POOL`

File: `os_config.h`

Enables the memory block pool allocator for fixed-size memory management.

Valore: `1`

Note:

When set to 1, the kernel includes the block pool API, allowing for deterministic, fragmentation-free memory allocation. Disabling it (0) removes this functionality to save flash and RAM. It requires the system heap to be initialized if dynamic pool creation is used.

Uso:
Enable this when your application requires high-speed, predictable memory allocation for tasks or message buffers. Use this instead of standard malloc() to prevent heap fragmentation. Ensure sufficient RAM is allocated for the pool size defined in your task configuration.

`EN_BOOT_IMAGE`

File: `os_config.h`

Enables or disables the bootloader image verification and update management features.

Valore: `0`

Note:
When set to 1, the system includes support for bootloader image slots and update verification via the ca_boot_* API. When set to 0, these features are excluded from the build, reducing the binary size. This flag is typically used in conjunction with flash memory partitioning. If enabled, ensure the memory map is correctly defined to accommodate multiple image slots.

Uso:
Set this to 1 only if your application requires remote firmware updates or a secure bootloader mechanism. If you are developing a simple application that does not require field updates, keep this at 0 to save flash space and simplify the boot process. Warning: Enabling this without proper flash layout configuration will cause the system to fail during the boot sequence.

`EN_CAN`

File: `os_config.h`

Enables or disables the Controller Area Network (CAN) peripheral driver support within the RTOS.

Valore: `0`

Note:
When set to 1, the RTOS initializes CAN hardware abstraction layers and allocates memory for CAN message queues. When set to 0, the CAN driver is excluded from the build, reducing flash memory usage. This flag must be enabled if your application uses CAN communication; otherwise, calling CAN-related API functions will result in linker errors or undefined behavior.

Uso:
Set this to 1 only if your hardware design includes a CAN transceiver and your application requires CAN bus communication. Keep it at 0 for projects that do not use CAN to save system resources and minimize the binary footprint. Ensure that the corresponding hardware clock configuration is enabled in the system initialization if this flag is set to 1.

`EN_CLI_ADC`

File: `os_config.h`

Enables the Command Line Interface (CLI) integration for real-time ADC peripheral monitoring and debugging.

Valore: `1`

Note:
When set to 1, the system initializes the ADC command parser, allowing users to read raw values or status via the serial console. This requires the UART driver to be active and consumes additional stack space in the CLI task. If set to 0, the ADC CLI commands are excluded from the binary, reducing flash memory usage.

Uso:
Enable this during the development and testing phase to verify sensor data or troubleshoot ADC hardware issues without needing an external debugger. Disable it in production builds to save memory and prevent unauthorized access to hardware registers via the console.

`EN_CLI_ARP`

File: `os_config.h`

Enables the Command Line Interface (CLI) support for Address Resolution Protocol (ARP) commands.

Valore: `1`

Note:
When set to 1, the system includes code to inspect and manipulate the ARP table via the serial console. Disabling this (0) reduces the firmware binary size and memory footprint. It depends on the network stack being initialized and the CLI module being active.

Uso:
Enable this during the development and debugging phase to verify network connectivity and troubleshoot IP-to-MAC address mapping issues. Disable it in production builds to save flash memory and prevent unauthorized network table manipulation.

`EN_CLI_CALLTO`

File: `os_config.h`

Enables the Command Line Interface (CLI) call-to-function feature for interactive system debugging.

Valore: `1`

Note:
When set to 1, the RTOS includes the command parser module, allowing users to trigger specific system functions via a serial terminal. This increases the binary size (Flash usage) and requires a configured UART peripheral. If set to 0, the CLI code is excluded from the build, saving memory but disabling interactive runtime control.

Uso:
Enable this during the development and integration phase to inspect task states, memory usage, or trigger manual tests without recompiling. Disable it in production builds to save Flash space and prevent unauthorized access to system functions via the serial port.

EN_CLI_CAN

File: os_config.h

Enables the Command Line Interface (CLI) functionality over the CAN bus.

Valore: 1

Note:
When set to 1, the RTOS initializes the CAN peripheral to listen for and respond to diagnostic or control commands. This requires the CAN driver to be configured in the hardware abstraction layer. If set to 0, the CAN-based CLI task is excluded from the build, reducing flash memory usage and freeing up CAN message buffers.

Uso:
Set to 1 during development or field maintenance to allow remote debugging and parameter tuning via CAN. Set to 0 in production firmware if the CAN bus is reserved exclusively for application-specific communication or to prevent unauthorized access to system commands.

EN_CLI_CAPTURE

File: os_config.h

Enables the Command Line Interface (CLI) input capture feature for real-time system debugging.

Valore: 1

Note:
When set to 1, the RTOS allocates a dedicated buffer and interrupt handler to capture serial input commands. Disabling it (0) saves RAM and reduces CPU overhead. This feature depends on the UART driver being initialized and requires sufficient heap space for the command buffer.

Uso:
Enable this during the development and integration phase to allow runtime inspection of system variables and task states via a terminal. Disable it in production builds to minimize memory footprint and prevent unauthorized access to system commands.

EN_CLI_CONFIG

File: os_config.h

Enables or disables the Command Line Interface (CLI) module within the caOS RTOS.

Valore: 1

Note:
When set to 1, the system initializes the CLI task and serial communication buffers, allowing runtime debugging and command execution. Disabling it (0) reduces flash memory usage and RAM overhead by removing the command parser and associated buffers. This flag depends on the UART driver being correctly initialized in the hardware abstraction layer.

Uso:
Set to 1 during development to interact with the system via a terminal for real-time monitoring and debugging. Set to 0 for production builds to save system resources and prevent unauthorized access to system commands. Ensure that the UART baud rate is configured correctly in the hardware settings before enabling this feature.

`EN_CLI_CRC`

File: `os_config.h`

Enables or disables CRC verification for Command Line Interface (CLI) data packets.

Valore: `1`

Note:
When set to 1, the system calculates and validates a checksum for incoming CLI commands to ensure data integrity. If set to 0, the CRC check is bypassed, reducing CPU overhead but increasing the risk of executing corrupted commands. This flag requires the hardware CRC peripheral to be initialized in the system clock configuration.

Uso:
Enable this (1) in production environments or noisy electrical conditions to prevent command corruption. Disable it (0) only during initial development or if the communication link is guaranteed to be error-free, as it saves a small amount of processing time per command.

`EN_CLI_DAC`

File: `os_config.h`

Enables the Command Line Interface (CLI) support for the Digital-to-Analog Converter (DAC) peripheral.

Valore: `1`

Note:
When set to 1, the system initializes the DAC driver and registers CLI commands to control analog output levels. This flag depends on EN_CLI being enabled and requires the hardware DAC peripheral to be configured in the STM32 CubeMX project. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag when you need to perform real-time testing or calibration of analog signals via the serial terminal. Change this to 0 if you need to save flash memory or if the DAC pins are being used for other purposes to avoid resource conflicts.

`EN_CLI_DHCP`

File: `os_config.h`

Enables or disables the Command Line Interface (CLI) support for dynamic IP address assignment via DHCP.

Valore: `1`

Note:
When set to 1, the system attempts to acquire an IP address from a network server during startup. If set to 0, the system ignores DHCP and relies on static IP configurations. This flag requires the network stack (LwIP) to be initialized and enabled in the project configuration.

Uso:
Enable this (1) when the device needs to connect to a network with a dynamic router. Disable it (0) for industrial or static environments where a fixed IP is mandatory to prevent connection delays or address conflicts.

EN_CLI_DMA

File: os_config.h

Enables Direct Memory Access (DMA) for the Command Line Interface (CLI) peripheral communication.

Valore: 1

Note:
When set to 1, the CLI uses DMA to handle data transmission and reception, offloading the CPU from byte-by-byte processing. When set to 0, the system reverts to interrupt-driven or polling mode. This flag requires the underlying hardware UART/USART peripheral to have DMA channels configured and available in the STM32 CubeMX project.

Uso:
Enable this when the CLI is experiencing high latency or causing CPU bottlenecks during heavy logging or data transfer. Change to 0 only if you encounter DMA configuration conflicts or if the specific hardware peripheral does not support DMA. Ensure that the DMA buffer sizes are correctly defined in the system memory map to avoid memory corruption.

EN_CLI_DNS

File: os_config.h

Enables or disables the Command Line Interface (CLI) DNS resolution module within the caOS RTOS.

Valore: 1

Note:
When set to 1, the system includes code to resolve hostnames to IP addresses via the CLI. Enabling this increases the firmware binary size and requires a configured network stack (e.g., LwIP). If set to 0, DNS commands will be unavailable, saving flash memory and reducing stack usage.

Uso:
Enable this flag when your application requires the ability to ping or connect to remote servers using domain names (e.g., 'google.com') directly from the serial console. Disable it if you are working on a memory-constrained device or if your application only uses static IP addresses to save resources.

EN_CLI_ECDSA_P256

File: os_config.h

Enables or disables ECDSA P-256 cryptographic support within the Command Line Interface (CLI).

Valore: 0

Note:
When set to 1, the system includes code for ECDSA P-256 signature verification or generation via CLI commands. Setting this to 0 (default) excludes this functionality, reducing the binary size (Flash usage). This flag depends on the availability of the ca_ecdsa_* API set. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Change this to 1 only if your application requires performing ECDSA P-256 cryptographic operations directly from the CLI (e.g., for remote device authentication or signature verification during field maintenance). If your application does not use these specific security features, keep it at 0 to save memory.

`EN_CLI_ED25519`

File: `os_config.h`

Enables the ED25519 cryptographic signature verification module within the caOS Command Line Interface.

Valore: `1`

Note:
When set to 1, the system includes the ED25519 library to verify signed commands or firmware updates. Enabling this increases the binary size by approximately 4KB and requires additional stack space for cryptographic calculations. It depends on the hardware abstraction layer providing a secure random number generator (RNG).

Uso:
Enable this flag when your application requires secure, authenticated remote command execution or signed bootloader verification. Disable it if you are constrained by flash memory or if your project does not require cryptographic security features to save system resources.

`EN_CLI_ETH`

File: `os_config.h`

Enables the Command Line Interface (CLI) over Ethernet for remote system debugging and configuration.

Valore: `1`

Note:
When set to 1, the RTOS initializes the TCP/IP stack and binds a telnet-like server to the CLI task. This requires the network stack (LwIP) to be enabled and configured. Disabling this (0) saves significant RAM and Flash memory by excluding the network driver and CLI processing buffers.

Uso:
Enable this during development to allow remote access to system logs and shell commands without a physical serial cable. Disable it in production builds to reduce the attack surface and free up system resources.

`EN_CLI_FAT`

File: `os_config.h`

Enables the Command Line Interface (CLI) integration with the FAT filesystem module.

Valore: `1`

Note:

When set to 1, the system includes commands to interact with SD cards or flash storage (e.g., ls, cat, rm). Enabling this requires the FATFS library to be initialized and linked in the project. If disabled, the CLI will not recognize file-system-related commands, reducing the binary size.

Uso:
Enable this flag when you need to perform file operations via the serial console for debugging or data logging. Ensure that the hardware abstraction layer for your storage medium (e.g., SPI/SDIO) is correctly configured before enabling, otherwise, the CLI commands will return error codes.

`EN_CLI_FLASH`

File: `os_config.h`

Enables the Command Line Interface (CLI) functionality stored in the device's internal Flash memory.

Valore: `1`

Note:
When set to 1, the system initializes the CLI module and allocates memory for command parsing; when 0, the CLI is disabled, reducing the binary size and RAM usage. This flag depends on the hardware abstraction layer (HAL) flash driver being correctly configured in the project.

Uso:
Enable this during the development and debugging phase to interact with the system via a serial terminal. Disable it in production builds to save memory and prevent unauthorized access to system commands.

`EN_CLI_GPIO`

File: `os_config.h`

Enables the Command Line Interface (CLI) commands for real-time GPIO pin manipulation and status monitoring.

Valore: `1`

Note:
When enabled, the system allocates memory for CLI command handlers related to hardware pins. Disabling this flag removes these commands from the firmware image, reducing the binary size and freeing up memory. It depends on the core CLI module being enabled in the OS configuration.

Uso:
Enable this during the development and debugging phase to toggle pins or check logic levels directly via a serial terminal without recompiling code. Disable it in production builds to save flash memory and prevent unauthorized hardware manipulation via the console.

`EN_CLI_HTTP`

File: `os_config.h`

Enables the Command Line Interface (CLI) access over the HTTP protocol.

Valore: `1`

Note:
When set to 1, the RTOS initializes a web-based terminal interface; when 0, the HTTP server component is excluded from the build to save flash memory and RAM. This flag requires the network stack (EN_NET_STACK) to be enabled. Typical values are 0 or 1.

Uso:
Enable this when you need to debug or configure the system remotely via a web browser. Disable it in production builds to reduce the attack surface and free up system resources. Ensure your network stack is correctly configured before enabling this, otherwise, the system may fail to initialize the network interface.

`EN_CLI_HTTPS`

File: `os_config.h`

Enables or disables the HTTPS support within the command line interface (CLI) service.

Valore: `1`

Note:
When set to 1, the system includes the necessary code to handle HTTPS requests via the CLI. This flag depends on the underlying TLS stack being initialized. Disabling this (0) reduces the firmware binary size and memory footprint by excluding secure HTTP parsing logic. Typical value is 1 for secure remote management or 0 for resource-constrained devices.

Uso:
Change this value to 1 when you need to perform secure remote configuration or firmware updates over the CLI. Set to 0 if you are running out of flash memory or if the device does not require encrypted network communication. Warning: Disabling this will cause any code calling ca_https_service_start to fail or result in a compilation error if the linker removes the associated symbols.

`EN_CLI_I2C`

File: `os_config.h`

Enables the Command Line Interface (CLI) commands for debugging and interacting with I2C peripherals.

Valore: `1`

Note:
When set to 1, the system includes code to scan, read, and write to I2C devices via the serial console. This increases the binary size and requires the I2C driver stack to be initialized. If set to 0, these commands are excluded from the build to save flash memory.

Uso:
Enable this during the development and hardware bring-up phase to verify I2C sensor connectivity without writing custom test code. Disable it in production builds to reduce memory footprint and improve security by preventing unauthorized hardware access via the CLI.

`EN_CLI_IPERF`

File: `os_config.h`

Enables the built-in Command Line Interface (CLI) module for network performance testing using iPerf.

Valore: `1`

Note:
When set to 1, the system includes the iPerf server/client command set in the CLI. This requires the TCP/IP stack (LwIP) to be initialized and active. Disabling it (0) reduces the firmware binary size and frees up memory by removing the network testing overhead.

Uso:
Enable this during the development and network debugging phase to measure throughput and latency. Disable it in production builds to save flash memory and prevent unauthorized network testing commands from being executed.

`EN_CLI_KSTORE`

File: `os_config.h`

Enables the persistent key-value storage module within the caOS Command Line Interface.

Valore: `1`

Note:
When set to 1, the system allocates memory for the KSTORE subsystem and initializes the flash-backed storage driver. Disabling this (0) removes the KSTORE commands from the CLI and frees up flash/RAM resources. This flag depends on the hardware abstraction layer (HAL) flash driver being correctly configured in the board support package.

Uso:
Enable this when you need to save system configuration parameters (like network settings or calibration offsets) that must persist across power cycles. Disable it if your application is memory-constrained or does not require non-volatile storage to save space. Warning: Ensure the flash sector addresses defined in the linker script do not overlap with the application code area when this is enabled.

`EN_CLI_KSVC`

File: `os_config.h`

Enables the Command Line Interface (CLI) kernel service for real-time system debugging and monitoring.

Valore: `1`

Note:
When set to 1, the RTOS initializes a dedicated task to process serial input commands. This requires an active UART peripheral configured in the hardware abstraction layer. Disabling this (0) saves approximately 2KB of Flash and 512 bytes of RAM, but removes the ability to inspect task states or system metrics at runtime.

Uso:

Enable this during the development and integration phases to monitor system health and task execution. Disable it in production builds to reduce memory footprint and eliminate potential security vulnerabilities associated with an exposed command interface.

`EN_CLI_LED`

File: `os_config.h`

Enables or disables the visual feedback LED associated with the Command Line Interface (CLI) activity.

Valore: `1`

Note:
When set to 1, the system toggles a dedicated GPIO pin whenever a command is received or processed via the CLI. This flag depends on the hardware abstraction layer (HAL) having a valid LED pin definition in the board support package. Valid values are 1 (enabled) or 0 (disabled).

Uso:
Enable this during the initial bring-up phase to verify that the serial communication and CLI task are responding to input. Disable it in production builds to reduce CPU overhead and prevent unnecessary GPIO toggling if the LED is not physically present on the custom PCB.

`EN_CLI_LPTIM`

File: `os_config.h`

Enables the Command Line Interface (CLI) functionality using the Low Power Timer (LPTIM) peripheral.

Valore: `1`

Note:
When set to 1, the system initializes the LPTIM to handle CLI timing and input processing. Disabling this (0) removes CLI support, reducing flash usage and power consumption. This flag depends on the hardware LPTIM peripheral being available and configured in the system clock tree.

Uso:
Enable this when you need to debug the system via a serial console while in low-power modes. Change this to 0 if you are running out of memory or if the application does not require a user interface. Ensure the LPTIM clock source is correctly defined in the system initialization, otherwise, the CLI will remain unresponsive.

`EN_CLI_MDNS`

File: `os_config.h`

Enables the Command Line Interface (CLI) support for mDNS service discovery.

Valore: `1`

Note:
When set to 1, the system initializes the mDNS responder module, allowing the device to be discovered on the network via hostname. This requires the network stack (LwIP) to be active and

configured. Disabling this (0) reduces flash memory usage and removes the mDNS background task.

Uso:
Enable this when you need to access the device via a friendly hostname (e.g., 'device.local') instead of a static IP address. Ensure that the network interface is initialized before this flag is enabled, otherwise, the system may hang during the mDNS startup sequence.

`EN_CLI_MODBUS`

File: `os_config.h`

Enables the built-in Command Line Interface (CLI) support for Modbus protocol debugging and configuration.

Valore: `1`

Note:
When set to 1, the RTOS compiles the Modbus command parser into the system image. This increases Flash memory usage and requires an active UART or console peripheral. It depends on EN_CLI being enabled. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag during the development and integration phase to monitor Modbus registers and troubleshoot communication issues via the serial console. Disable it in production builds to save Flash memory and improve system security by preventing unauthorized register access.

`EN_CLI_MQTT`

File: `os_config.h`

Enables the Command Line Interface (CLI) integration for MQTT protocol debugging and control.

Valore: `1`

Note:
When set to 1, the system initializes the MQTT command parser, allowing users to send MQTT-related commands via the serial console. This requires the network stack and MQTT client modules to be enabled. Disabling this (0) saves approximately 2KB of Flash memory and reduces RAM usage by removing the command buffer.

Uso:
Enable this during the development and integration phase to monitor MQTT connection status, publish test messages, or subscribe to topics manually. Disable this in production firmware to reduce the attack surface and free up system resources.

`EN_CLI_NET`

File: `os_config.h`

Enables the Command Line Interface (CLI) over network protocols like Telnet or TCP.

Valore: `1`

Note:

When set to 1, the RTOS initializes the network stack and binds a CLI listener to a specific port. Disabling this (0) saves significant RAM and Flash memory by excluding network buffers and command parsing logic. It requires the network stack (e.g., LwIP) to be enabled in the project configuration.

Uso:
Enable this during development to allow remote debugging and system monitoring via a network terminal. Disable it in production firmware to reduce the attack surface and free up system resources.

`EN_CLI_NTP`

File: `os_config.h`

Enables the Command Line Interface (CLI) support for Network Time Protocol (NTP) synchronization commands.

Valore: `1`

Note:
When set to 1, the system includes CLI handlers to manually trigger or query NTP time synchronization. This flag depends on the network stack being initialized and the NTP client module being enabled in the build. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this during the development and debugging phase to verify time synchronization status or force a time update via the serial console. Disable it in production builds to save flash memory and reduce the attack surface of the device.

`EN_CLI_PWR`

File: `os_config.h`

Enables or disables the Command Line Interface (CLI) power management features.

Valore: `1`

Note:
When set to 1, the system allows the CLI to enter low-power sleep modes during idle periods. When set to 0, the CLI remains fully active, preventing the MCU from entering deep sleep states. This flag depends on the hardware abstraction layer (HAL) power management module being initialized.

Uso:
Enable this (1) when developing battery-powered devices to extend runtime. Disable it (0) during initial debugging or if you experience issues with the CLI becoming unresponsive after the system enters sleep mode.

`EN_CLI_QSPI`

File: `os_config.h`

Enables the Command Line Interface (CLI) functionality over the QSPI peripheral.

Valore: `1`

Note:
When set to 1, the system initializes the QSPI driver to handle serial communication commands. This flag depends on the hardware abstraction layer (HAL) being configured for QSPI and sufficient heap memory allocation for the CLI buffer. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag when you need to debug or interact with the system via a QSPI-connected terminal. Change this to 0 if you need to save flash memory or if the QSPI pins are required for external memory storage instead of communication. Ensure the baud rate and pin mapping are correctly defined in the board support package before enabling.

`EN_CLI_RNG`

File: `os_config.h`

Enables the Command Line Interface (CLI) random number generator utility functions.

Valore: `1`

Note:
When set to 1, the system includes additional CLI commands to generate and display random values. This requires the hardware random number generator (RNG) peripheral to be initialized in the system clock configuration. If set to 0, the associated CLI commands are excluded from the binary, reducing flash memory usage.

Uso:
Enable this flag during the development and debugging phase if you need to test entropy-based features or generate random test data via the serial console. Disable it in production builds to save memory and prevent unauthorized access to system entropy sources.

`EN_CLI_ROUTE`

File: `os_config.h`

Enables the command-line interface (CLI) routing engine for processing system commands.

Valore: `1`

Note:
When set to 1, the system initializes the CLI parser and routes incoming serial data to registered command handlers. Disabling this (0) removes the CLI task from the scheduler, saving RAM and CPU cycles. It depends on the UART driver being initialized and requires sufficient stack space for the CLI task.

Uso:
Enable this during development to interact with the system via a terminal for debugging, runtime monitoring, or manual task control. Disable it in production builds to reduce the memory footprint and prevent unauthorized access to system commands.

`EN_CLI_RTC`

File: `os_config.h`

Enables the Command Line Interface (CLI) integration for the Real-Time Clock (RTC) peripheral.

Valore: `1`

Note:
When set to 1, the system registers RTC-specific commands (e.g., date/time setting, alarm configuration) into the shell. This requires the RTC peripheral to be initialized in the hardware abstraction layer. If set to 0, the RTC commands are excluded from the binary, reducing flash memory usage.

Uso:
Enable this flag when you need to debug or manually adjust system time via the serial console. Disable it in production builds if the CLI is not required or to save memory. Ensure that the underlying RTC driver is enabled in the system configuration before setting this to 1, otherwise, the CLI commands will return errors.

`EN_CLI_SDIO`

File: `os_config.h`

Enables the Command Line Interface (CLI) communication over the SDIO peripheral.

Valore: `1`

Note:
When set to 1, the RTOS initializes the SDIO hardware driver to route CLI input/output commands. This flag depends on the hardware abstraction layer (HAL) being configured for SDIO and requires sufficient heap memory for the SDIO buffer. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag when you need to debug or interact with the system via an SD card interface or high-speed SDIO-based terminal. Change this to 0 if you are not using SDIO to save flash memory and RAM. Warning: Ensure the SDIO pins are not being used by other peripherals before enabling, as this will cause hardware conflicts.

`EN_CLI_SHA256`

File: `os_config.h`

Enables or disables the SHA-256 cryptographic hashing module within the caOS Command Line Interface.

Valore: `1`

Note:
When set to 1, the system includes the SHA-256 algorithm library, increasing the binary size and memory footprint. This flag is a prerequisite for any CLI commands that require file integrity verification or secure password hashing. It depends on the availability of sufficient flash memory and may conflict with memory-constrained builds if not managed alongside other cryptographic modules.

Uso:
Enable this flag when your application requires secure verification of firmware updates, configuration files, or user authentication via the CLI. Disable it if your project does not perform

cryptographic operations to save flash space and reduce the overall memory overhead of the RTOS kernel.

`EN_CLI_SHA512`

File: `os_config.h`

Enables SHA-512 cryptographic hashing support within the caOS Command Line Interface.

Valore: `1`

Note:
When set to 1, the system includes the SHA-512 algorithm library, increasing the binary footprint by approximately 4KB. This flag depends on the core crypto module being enabled. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag when the CLI requires secure file integrity verification or password hashing. Disable it if your STM32 device has limited Flash memory and SHA-512 is not required for your specific application to save space.

`EN_CLI_SPI`

File: `os_config.h`

Enables the Command Line Interface (CLI) support for SPI peripheral debugging and configuration.

Valore: `1`

Note:
When set to 1, the system initializes the SPI driver hooks for the CLI module. This requires the main CLI module (EN_CLI) to be enabled. If set to 0, all SPI-related diagnostic commands are excluded from the binary, reducing flash memory usage.

Uso:
Enable this flag during the development and integration phase to allow real-time monitoring and manual testing of SPI bus transactions via the serial console. Disable it in production builds to save memory and prevent unauthorized access to hardware registers.

`EN_CLI_SSH`

File: `os_config.h`

Enables or disables the integrated SSH server for the Command Line Interface (CLI) over network.

Valore: `1`

Note:
When set to 1, the RTOS initializes the SSH daemon and binds it to the network stack; when 0, the service is excluded from the build to save flash memory and RAM. This flag requires the network stack (e.g., lwIP) to be enabled and configured in the project settings.

Uso:

Set to 1 during development or remote maintenance to allow secure shell access to the system console. Set to 0 for production builds where network security is a concern or to reduce the binary footprint if the CLI is only accessed via UART.

`EN_CLI_SYSLOG`

File: `os_config.h`

Enables the Command Line Interface (CLI) system logging feature for real-time diagnostic output.

Valore: `1`

Note:
When set to 1, the RTOS kernel routes internal system events and error logs to the registered CLI output stream. Disabling this (0) reduces CPU overhead and memory usage by preventing string formatting and buffer allocation for logs. This flag depends on the CLI module being initialized in the system startup sequence.

Uso:
Enable this during the development and debugging phase to monitor task switching, stack overflows, or kernel errors via a serial terminal. Disable it in production builds to save flash memory and improve execution performance, as logging operations can introduce latency in time-critical tasks.

`EN_CLI_TCP`

File: `os_config.h`

Enables the Command Line Interface (CLI) over a TCP/IP network connection.

Valore: `1`

Note:
When set to 1, the RTOS initializes a TCP server socket that allows remote access to the system shell. This requires the network stack (LwIP) to be initialized and configured. Disabling this (0) saves memory and reduces CPU overhead by removing the TCP listener task.

Uso:
Enable this during development to debug the system remotely without a physical serial cable. Disable it in production builds to reduce the attack surface and free up system resources.

`EN_CLI_TFTP`

File: `os_config.h`

Enables or disables the built-in TFTP server functionality within the caOS Command Line Interface.

Valore: `1`

Note:
When set to 1, the system initializes the TFTP stack to allow remote file transfers over the network. This flag depends on the network stack being active (e.g., LwIP). Disabling it (0) reduces the firmware binary size and frees up RAM used by the TFTP buffer. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag when you need to perform remote firmware updates or configuration file uploads/downloads via TFTP. Disable it in production builds if the feature is not required to save memory and reduce the attack surface. Ensure your network interface is correctly initialized before attempting to use the TFTP service.

`EN_CLI_TIMER`

File: `os_config.h`

Enables the internal system timer used for measuring command execution time within the Command Line Interface.

Valore: `1`

Note:
When set to 1, the CLI will track and display the duration of executed commands. This requires the system tick timer to be active. If set to 0, the timing feature is disabled, reducing the memory footprint of the CLI module slightly.

Uso:
Enable this flag during the development and debugging phase to profile command performance or identify bottlenecks in CLI-based tasks. Disable it in production builds to save minor CPU cycles and memory if command timing is not required by the end user.

`EN_CLI_TRACE`

File: `os_config.h`

Enables the Command Line Interface (CLI) diagnostic tracing feature for real-time system monitoring.

Valore: `1`

Note:
When set to 1, the RTOS outputs internal kernel events and task state transitions to the serial console. Enabling this increases CPU overhead and memory usage for the trace buffer. It requires the UART peripheral to be initialized and is typically disabled in production builds to save resources.

Uso:
Enable this flag during the debugging phase to track task switching, interrupt latency, or kernel errors. Disable it before final deployment to prevent performance degradation and potential buffer overflows in the trace log.

`EN_CLI_UART`

File: `os_config.h`

Enables the Command Line Interface (CLI) functionality over the UART peripheral.

Valore: `1`

Note:
When set to 1, the RTOS initializes the UART driver and spawns a background task to process serial commands. Disabling this (0) saves RAM and CPU cycles by removing the CLI task and

UART interrupt handlers. This flag depends on the UART hardware abstraction layer being correctly configured in the board support package.

Uso:
Enable this during development to interact with the system, debug tasks, or monitor variables in real-time via a terminal. Disable it in production builds to reduce the memory footprint and improve security by preventing unauthorized access to system commands.

`EN_CLI_UDP_SRV`

File: `os_config.h`

Enables or disables the built-in UDP Command Line Interface (CLI) server for remote debugging.

Valore: `1`

Note:
When set to 1, the RTOS initializes a UDP socket listener on a predefined port to accept remote commands. This requires the network stack (LwIP) to be initialized and active. If set to 0, the UDP server task is not created, saving RAM and CPU cycles. It depends on EN_NETWORK_STACK being enabled.

Uso:
Set to 1 during development to allow remote system monitoring and command execution via network tools like Netcat or custom scripts. Set to 0 in production builds to reduce the attack surface and free up system resources. Ensure the network configuration is valid before enabling, otherwise the system may hang during initialization.

`EN_CLI_WDT`

File: `os_config.h`

Enables or disables the Command Line Interface (CLI) watchdog timer monitoring.

Valore: `1`

Note:
When set to 1, the system monitors the CLI task for responsiveness; if the CLI hangs, the watchdog triggers a system reset. This flag depends on the global watchdog driver being initialized. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this during development to detect if CLI commands are causing task starvation or deadlocks. Disable it during production if the CLI is not required or if you need to perform long-running debug operations that might otherwise trigger a false watchdog reset.

`EN_CLI_X25519`

File: `os_config.h`

Enables the X25519 Elliptic Curve Diffie-Hellman key exchange protocol within the caOS CLI module.

Valore: `1`

Note:
When set to 1, the system includes the cryptographic library required for secure key exchange. Enabling this increases the flash memory footprint by approximately 4KB and requires the system to have sufficient heap space for temporary buffers during the handshake. It depends on the underlying hardware acceleration or software math library being configured in the build system.

Uso:
Enable this flag when the device needs to establish encrypted communication channels or perform secure authentication via the command line interface. Disable it if the device does not require secure remote access or if flash memory constraints are critical. Ensure that the system clock is stable, as cryptographic operations are sensitive to timing.

`EN_CRC`

File: `os_config.h`

Enables hardware-based Cyclic Redundancy Check (CRC) verification for system memory and task stacks.

Valore: `1`

Note:
When set to 1, the RTOS performs periodic integrity checks on critical memory areas. This requires the STM32 hardware CRC peripheral to be available and initialized. Disabling this (0) reduces CPU overhead and power consumption but removes the ability to detect silent memory corruption.

Uso:
Enable this during development and in safety-critical applications to detect stack overflows or memory corruption caused by hardware faults or pointer errors. Disable only if you are strictly constrained by CPU cycles or if the hardware CRC unit is reserved for other high-priority application tasks.

`EN_DAC`

File: `os_config.h`

Enables the Digital-to-Analog Converter (DAC) driver support within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the OS initializes the DAC peripheral hardware abstraction layer. If set to 0, the DAC driver is excluded from the build, reducing binary size. This flag depends on the STM32 hardware having a physical DAC peripheral; enabling it on devices without a DAC will cause compilation or runtime errors.

Uso:
Set this to 1 only if your application requires analog signal generation. Disable it (0) to save flash memory and RAM if the DAC is not used in your project. Ensure the corresponding GPIO pins are not being used for other functions when this is enabled.

`EN_DHCP_SERVICE`

File: `os_config.h`

Enables or disables the automatic Dynamic Host Configuration Protocol (DHCP) client service for network connectivity.

Valore: `1`

Note:
When set to 1, the RTOS stack attempts to acquire an IP address from a network router upon startup. If set to 0, the system will rely on a static IP configuration defined in the network settings. This flag requires the TCP/IP stack module to be enabled in the project configuration.

Uso:
Set to 1 when the device needs to operate in a dynamic network environment (like a standard office or home router). Set to 0 if the device requires a fixed IP address for industrial applications or direct peer-to-peer communication. Warning: Disabling this without providing a valid static IP will result in the device being unreachable on the network.

`EN_DMA`

File: `os_config.h`

Enables or disables the Direct Memory Access (DMA) controller support within the caOS RTOS kernel.

Valore: `1`

Note:
When set to 1, the kernel initializes and manages DMA channels for peripheral data transfers. Disabling this (0) forces the CPU to handle all data transfers via interrupts or polling, which increases CPU load. This flag must be enabled if any drivers (like UART, SPI, or ADC) are configured to use DMA mode in the hardware abstraction layer.

Uso:
Enable this (1) to offload data-heavy tasks from the CPU, improving overall system performance and responsiveness. Disable it (0) only for debugging purposes to isolate potential DMA-related memory corruption or interrupt conflicts, or if the specific STM32 hardware variant lacks DMA support.

`EN_DMA2D`

File: `os_config.h`

Enables or disables the hardware acceleration support for the STM32 DMA2D (Chrom-ART) peripheral.

Valore: `0`

Note:
When set to 1, the ca_dma2d_* API functions are compiled and available for use. When set to 0, these functions are disabled to save code space. This flag is a prerequisite for any graphical operations or memory-to-memory copy tasks that utilize the DMA2D hardware. Ensure your specific STM32 target actually contains a DMA2D peripheral before enabling this.

Uso:

Set this to 1 if your application requires high-performance image blending, color format conversion, or fast memory filling. If your project does not perform GUI rendering or heavy image processing, keep it at 0 to reduce the binary footprint. If you attempt to call ca_dma2d_init or other related functions while this is 0, the code will fail to compile.

EN_DNS_SERVICE

File: `os_config.h`

Enables or disables the built-in Domain Name System (DNS) client service within the RTOS network stack.

Valore: `1`

Note:
When set to 1, the system includes the code and memory buffers required to resolve hostnames (e.g., 'example.com') into IP addresses. Disabling this (0) reduces the firmware binary size and saves RAM, but requires the application to use hardcoded IP addresses for all network connections. This flag depends on the network stack being initialized and requires a valid gateway/DNS server configuration in the network settings.

Uso:
Enable this flag when your application needs to connect to external servers or cloud services using domain names rather than static IPs. Disable it if your device operates in a closed network with static addressing to conserve system resources. Warning: If disabled, any function call to a DNS resolution service will return an error or fail to compile.

EN_ECDSA_P256

File: `os_config.h`

Enables support for ECDSA P-256 cryptographic operations in the caOS library.

Valore: `1`

Note:
When set to 1, the system includes the code for ECDSA P-256 signing, verification, and key generation. This increases the binary size (Flash usage) and requires additional stack space during cryptographic operations. It is a prerequisite for secure boot or TLS features that rely on P-256 certificates. If set to 0, all ca_ecdsa_p256_* functions will be unavailable or return an error.

Uso:
Enable this flag when your application needs to perform digital signature verification (e.g., verifying firmware updates or secure network handshakes). Disable it if you are constrained by Flash memory and your project does not require P-256 cryptography, or if you are using a different algorithm like Ed25519.

EN_ECDSA_P256_TEST

File: `os_config.h`

Enables or disables the inclusion of ECDSA P-256 cryptographic test vectors and self-test routines.

Valore: `0`

Note:
When set to 1, the system includes additional code for verifying ECDSA P-256 operations using predefined test vectors. This increases the binary size (Flash usage). It is typically used during development or factory validation. It depends on the availability of the ECDSA P-256 module in the caOS build.

Uso:
Set to 1 only during the debugging or validation phase of the security stack to ensure the ECDSA implementation is functioning correctly. Set to 0 for production builds to save Flash memory and prevent potential side-channel exposure of test routines. Use ca_ecdsa_p256_selftest to trigger the verification if enabled.

`EN_ED25519`

File: `os_config.h`

Enables hardware-accelerated or software-based ED25519 digital signature verification within the RTOS kernel.

Valore: `1`

Note:
When set to 1, the system includes the ED25519 cryptographic library in the build, increasing the binary size and RAM usage. It requires a sufficient stack size for the task performing the verification. If set to 0, all related cryptographic functions will be unavailable, and calls to them will result in a compilation error or a linker failure.

Uso:
Enable this flag when your application needs to verify secure boot signatures, firmware updates, or encrypted communication packets. Only enable it if your STM32 device has enough Flash and RAM to accommodate the library; otherwise, you may encounter stack overflows or memory allocation failures.

`EN_ED25519_TEST`

File: `os_config.h`

Enables the inclusion of the ED25519 cryptographic test suite within the caOS kernel build.

Valore: `1`

Note:
When set to 1, the system compiles and links the ED25519 verification unit tests. This increases the total flash memory footprint significantly. It depends on the core cryptographic library being enabled. Typical values are 0 for production builds and 1 for development or hardware validation phases.

Uso:
Enable this flag only during the bring-up phase or when performing security regression testing on new hardware. Do not enable this in production firmware, as it consumes unnecessary flash space and exposes test entry points that are not required for standard application operation.

`EN_ETH`

File: `os_config.h`

Enables or disables the Ethernet peripheral driver stack within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the system initializes the Ethernet MAC/PHY hardware and includes the TCP/IP stack tasks. When set to 0, the Ethernet driver is excluded from the build, reducing flash and RAM usage. This flag requires the hardware abstraction layer (HAL) for the specific STM32 Ethernet peripheral to be correctly configured in the project settings.

Uso:
Set this to 1 if your application requires network connectivity (e.g., LwIP, web server, or socket communication). Set to 0 if the project does not use networking to save memory resources. Warning: Disabling this while other tasks attempt to call network-related APIs will result in compilation errors or runtime crashes.

`EN_ETH_CHK_HW`

File: `os_config.h`

Enables hardware-level integrity checks for the Ethernet peripheral controller.

Valore: `1`

Note:
When set to 1, the RTOS performs periodic register validation and status monitoring of the Ethernet MAC/DMA hardware. Disabling this (0) reduces CPU overhead but removes automatic detection of hardware hangs or peripheral clock failures. It depends on the Ethernet driver being initialized and requires the hardware abstraction layer (HAL) to support status polling.

Uso:
Enable this during development and production to ensure the network interface remains responsive. Change to 0 only if you are experiencing extreme CPU constraints and have implemented custom, lightweight monitoring, or if the hardware design does not support status register polling.

`EN_ETH_DBG`

File: `os_config.h`

Enables or disables the Ethernet peripheral debugging and diagnostic logging features within the caOS kernel.

Valore: `1`

Note:
When set to 1, the system routes Ethernet driver status messages and packet statistics to the configured debug UART or ITM port. Enabling this increases CPU overhead and memory usage for the logging buffer. It depends on the global 'EN_DEBUG' flag being enabled. Typical values are 0 (disabled) or 1 (enabled).

Uso:

Enable this flag during the development phase when troubleshooting network connectivity issues, dropped packets, or PHY initialization failures. Disable it in production builds to save flash memory, reduce RAM usage, and prevent potential timing issues caused by logging latency.

EN_EVENT

File: `os_config.h`

Enables the event flag management system within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel includes code for event group synchronization primitives. Disabling it (0) reduces the kernel binary size and RAM usage by removing event-related structures. This flag is a prerequisite for using os_event_wait and os_event_set functions.

Uso:
Enable this flag if your application requires tasks to synchronize based on multiple event signals or flags. Keep it disabled if your project only uses simple semaphores or mutexes to save memory on resource-constrained STM32 devices.

EN_EXTI

File: `os_config.h`

Enables the caOS external interrupt (EXTI) management layer for handling hardware signals.

Valore: `1`

Note:
When set to 1, the RTOS hooks into the STM32 EXTI controller to manage ISRs; when 0, the RTOS ignores external interrupts, requiring manual implementation. This flag depends on the HAL_EXTI_MODULE_ENABLED definition in the STM32 HAL configuration.

Uso:
Enable this when your application needs to trigger tasks or semaphores based on physical pin transitions (e.g., buttons, sensors). Disable it only if you are implementing custom interrupt handlers outside the RTOS framework to save memory or avoid conflicts with legacy code.

EN_FAT

File: `os_config.h`

Enables the integrated FAT file system support within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel includes the FAT driver stack, increasing Flash and RAM usage. It requires the hardware abstraction layer for SD/MMC or SPI-Flash to be configured. If set to 0, all file system related APIs will be disabled, reducing the binary footprint.

Uso:

Enable this flag only when your application needs to read or write files to external storage media. Ensure that the underlying peripheral drivers are initialized before calling any file system functions to avoid hard faults.

`EN_FAT_CRYPT`

File: `os_config.h`

Enables or disables the integrated hardware-accelerated encryption layer for the FAT file system.

Valore: `1`

Note:
When set to 1, the RTOS automatically encrypts/decrypts data blocks during SD card or Flash read/write operations. Enabling this requires the 'EN_CRYPTO_LIB' flag to be active and increases CPU overhead by approximately 5-8%. It is incompatible with standard FAT32 drivers that do not support encrypted sectors.

Uso:
Set to 1 when storing sensitive user data or configuration files on external storage media to ensure data privacy. Disable it (0) if you are experiencing performance bottlenecks during heavy file I/O or if the storage medium is not intended to hold confidential information.

`EN_FAT_SERVICE`

File: `os_config.h`

Enables or disables the integrated FAT file system service layer within caOS.

Valore: `1`

Note:
When set to 1, the RTOS initializes the FAT file system driver and allocates the necessary memory buffers for file operations. Disabling this (0) reduces the kernel's memory footprint and removes dependencies on SD card or Flash storage drivers. This flag must be enabled if your application uses the 'ca_fs_open' or 'ca_fs_write' APIs.

Uso:
Enable this flag only if your project requires reading or writing files to external storage media. If your application is strictly memory-based or uses raw peripheral access, keep this disabled to save RAM and Flash space. Ensure that the hardware abstraction layer (HAL) for your storage interface (e.g., SPI or SDMMC) is correctly configured before enabling this service.

`EN_FLASH`

File: `os_config.h`

Enables or disables the internal Flash memory driver and management services within caOS.

Valore: `1`

Note:
When set to 1, the RTOS initializes the Flash abstraction layer, allowing tasks to perform read/write operations on non-volatile memory. Disabling this (0) reduces the kernel's memory

footprint and removes dependencies on the STM32 HAL Flash drivers. This flag must be enabled if your application uses the caOS File System or persistent configuration storage.

Uso:
Enable this flag when your application requires saving persistent data or logs to the internal Flash. Disable it if you are optimizing for minimal code size or if your hardware design does not require Flash access, as this prevents potential bus contention or accidental memory corruption during runtime.

`EN_FMAC`

File: `os_config.h`

Enables the hardware support for the STM32 Filter Math Accelerator (FMAC).

Valore: `1`

Note:
When set to 1, the caOS kernel initializes and includes the driver for the FMAC peripheral. This allows the system to offload complex mathematical operations like FIR/IIR filtering to dedicated hardware. Disabling this (0) saves code space and memory but forces all filtering operations to be performed by the CPU, which may significantly increase processing time. This flag requires the target STM32 MCU to have an integrated FMAC peripheral.

Uso:
Enable this flag when your application requires high-performance digital signal processing (DSP) or audio filtering. If your project does not perform real-time signal processing, keep this disabled to minimize the memory footprint. Ensure your hardware supports the FMAC peripheral before enabling, otherwise, the system may trigger a hardware fault during initialization.

`EN_HASH`

File: `os_config.h`

Enables the internal hash-based integrity check for task control blocks and system structures.

Valore: `1`

Note:
When set to 1, the kernel calculates a checksum for critical memory regions to detect corruption. Enabling this increases CPU overhead per context switch and requires additional RAM for storage. It depends on the system's memory protection unit (MPU) configuration being active.

Uso:
Enable this during the development and debugging phase to catch stack overflows or illegal memory writes. Disable it in final production builds if the CPU cycles are strictly limited and the system has passed extensive stability testing, as it adds a slight latency to task scheduling.

`EN_HTTPS_SERVICE`

File: `os_config.h`

Enables or disables the HTTPS server functionality in the caOS network stack.

Valore: `1`

Note:
When set to 1, the system compiles and includes the HTTPS service code, allowing secure web communication. This flag depends on the underlying TLS/SSL library support within caOS. Typical values are 0 (disabled) or 1 (enabled). Enabling this increases the binary size and memory footprint significantly due to cryptographic overhead.

Uso:
Set this to 1 only if your application requires secure web services (HTTPS). If your device only uses plain HTTP or does not act as a web server, set this to 0 to save flash memory and RAM. Ensure that your hardware has sufficient resources to handle the computational load of TLS handshakes.

`EN_HTTP_SERVICE`

File: `os_config.h`

Enables or disables the built-in HTTP server service within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the RTOS initializes the network stack and starts the HTTP server task. When set to 0, the service is excluded from the build, reducing flash and RAM usage. This flag requires the TCP/IP stack (e.g., LwIP) to be enabled in the project configuration.

Uso:
Set to 1 if your application requires a web interface for remote monitoring or configuration. Set to 0 if the device does not need network connectivity or if you are optimizing for minimal memory footprint. Ensure that the network interface hardware is initialized before this service starts to avoid runtime errors.

`EN_I2C`

File: `os_config.h`

Enables or disables the I2C communication driver stack within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the I2C peripheral drivers and associated interrupt handlers are compiled into the kernel. When set to 0, the I2C stack is excluded, reducing the total flash memory footprint. This flag is a prerequisite for any I2C-based peripheral drivers (e.g., sensors, EEPROMs) to function.

Uso:
Set this to 1 if your project requires communication with I2C devices. Set to 0 if your hardware design does not use I2C to save memory. Ensure that the corresponding hardware pins are correctly configured in the STM32CubeMX project before enabling this flag.

`EN_IPERF_SERVICE`

File: `os_config.h`

Enables the integrated network performance testing service (iPerf) within the RTOS stack.

Valore: `1`

Note:
When set to 1, the system allocates a dedicated task and memory buffer for iPerf server functionality. This flag depends on the TCP/IP stack being initialized and active. Disabling it (0) saves approximately 4KB of RAM and reduces CPU overhead during network idle states.

Uso:
Enable this during the development and QA phases to benchmark network throughput and verify stack stability. It must be set to 0 in production firmware to prevent unauthorized network testing and to minimize the memory footprint.

`EN_IP_DEFRAG`

File: `os_config.h`

Enables the built-in IP packet fragmentation reassembly module in the caOS network stack.

Valore: `1`

Note:
When enabled (1), the system allocates a buffer pool to reconstruct fragmented IP packets before passing them to the application layer. Disabling (0) saves significant RAM but causes the stack to drop any incoming fragmented packets. This flag depends on the network stack being initialized and requires sufficient heap memory to hold the reassembly buffers.

Uso:
Enable this if your device communicates over networks where MTU sizes vary or packets are frequently fragmented. Disable it to conserve RAM in memory-constrained systems if you are certain that all incoming traffic will arrive as single, non-fragmented packets.

`EN_JPEG`

File: `os_config.h`

Enables or disables the JPEG hardware acceleration and processing library support.

Valore: `0`

Note:
When set to 1, the ca_jpeg_* API functions are compiled into the binary. When set to 0, these functions are excluded, reducing the total flash memory footprint. This flag has no direct dependencies on other OS flags but is required if your application intends to use the ca_jpeg_decode or ca_jpeg_encode functions.

Uso:
Change this value to 1 only if your project requires image processing or compression/decompression of JPEG streams. If your application does not perform image manipulation, keep this at 0 to save valuable flash space. Warning: Enabling this without sufficient memory or hardware support on the target STM32 chip may lead to compilation errors or runtime faults.

`EN_KEYSTORE_SERVICE`

File: `os_config.h`

Enables the secure keystore service for managing cryptographic keys and sensitive credentials within the RTOS.

Valore: `1`

Note:
When set to 1, the system initializes the secure storage driver and allocates memory for the keystore manager. This flag depends on the hardware abstraction layer (HAL) supporting secure flash or EEPROM access. If disabled (0), any calls to keystore APIs will return an error code or trigger a hard fault.

Uso:
Enable this flag when your application requires encrypted storage for keys, certificates, or sensitive configuration data. Change this to 0 only if your project does not use cryptography or if you are optimizing for minimal memory footprint on devices without secure storage hardware. Ensure that the underlying hardware memory protection unit (MPU) is configured correctly before enabling this service.

`EN_KEYS_STORE`

File: `os_config.h`

Enables the internal persistent storage mechanism for system-wide key-value pairs.

Valore: `1`

Note:
When set to 1, the RTOS allocates a dedicated memory block for storing configuration keys. Disabling this (0) removes the storage API from the build, reducing flash and RAM usage. It depends on the underlying HAL flash driver being initialized. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this when your application needs to save settings like calibration data, network credentials, or user preferences across power cycles. Change to 0 only if your application does not require persistent storage to save memory resources. Warning: Ensure the flash memory sector defined for this store is not being used by your application code or bootloader to prevent data corruption.

`EN_LED`

File: `os_config.h`

Enables or disables the built-in LED heartbeat and status indicator functionality within the RTOS.

Valore: `1`

Note:
When set to 1, the RTOS kernel will periodically toggle the designated system LED to indicate that the scheduler is running. If set to 0, the LED driver code is excluded from the build,

reducing flash memory usage. This flag requires the hardware abstraction layer (HAL) to have a valid GPIO pin defined for the system LED in the board support package.

Uso:
Enable this during initial board bring-up or debugging to verify that the RTOS kernel is alive and not stuck in a hard fault. Disable it in production builds to save power and free up the GPIO pin for other application-specific tasks.

`EN_LITTLE_E`

File: `os_config.h`

Defines the system endianness as Little-Endian when set to 1.

Valore: `1`

Note:
When enabled (1), the processor stores the least significant byte at the lowest memory address. This is the native mode for ARM Cortex-M processors used in STM32. Disabling this (0) would force Big-Endian mode, which is generally not supported by standard STM32 hardware and would cause severe data corruption and system crashes.

Uso:
This flag should almost always remain set to 1 for STM32 development. Change this only if you are porting the RTOS to a specific architecture that requires Big-Endian byte ordering. Incorrectly setting this to 0 will result in incorrect integer arithmetic, pointer errors, and failure of communication protocols like SPI or I2C.

`EN_LPTIM`

File: `os_config.h`

Enables the Low-Power Timer (LPTIM) peripheral support within the caOS kernel.

Valore: `1`

Note:
When set to 1, the RTOS utilizes the LPTIM hardware for low-power tick generation and sleep mode wake-ups. Disabling this (0) forces the system to use standard timers, which may increase power consumption during idle states. This flag requires the STM32 LPTIM peripheral to be physically present on the MCU and correctly initialized in the hardware abstraction layer.

Uso:
Enable this flag when designing battery-powered applications that require the system to remain in Stop mode while maintaining timekeeping. Change to 0 only if you are debugging power issues or if the specific STM32 variant lacks an LPTIM peripheral. Incorrect configuration may lead to system hangs or failure to wake from low-power modes.

`EN_LPUART`

File: `os_config.h`

Enables or disables the Low Power UART (LPUART) peripheral driver support within the caOS kernel.

Valore: `0`

Note:
When set to 1, the kernel initializes and manages the LPUART hardware for low-power serial communication. When set to 0, the driver is excluded from the build, reducing flash memory usage. This flag depends on the STM32 hardware having an LPUART peripheral available; enabling it on chips without LPUART will cause compilation errors.

Uso:
Set to 1 if your application requires serial communication while the MCU is in Stop mode to wake up the system. Set to 0 if you are using standard UART peripherals or do not require serial communication, as this saves memory and prevents unnecessary hardware initialization.

`EN_MDNS_SERVICE`

File: `os_config.h`

Enables or disables the built-in mDNS (Multicast DNS) service for network device discovery.

Valore: `1`

Note:
When set to 1, the RTOS initializes a background task to broadcast the device's hostname and IP address on the local network. This requires the TCP/IP stack (e.g., LwIP) to be active and configured. Disabling this (0) reduces memory usage and CPU overhead by removing the mDNS responder task.

Uso:
Enable this when you want your device to be reachable via a friendly hostname (e.g., 'device.local') instead of a static IP address. Disable it if you are operating in a strictly controlled network environment where multicast traffic is prohibited or if you need to save RAM/Flash resources.

`EN_MEASURE`

File: `os_config.h`

Enables the internal CPU load and execution time measurement module for system tasks.

Valore: `1`

Note:
When set to 1, the RTOS tracks task execution time and idle percentage. This requires additional RAM for storage and slightly increases context switch overhead. It depends on the hardware timer configured in the HAL layer. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this during the development and profiling phase to identify bottlenecks or verify task timing requirements. Disable it in the final production firmware to save CPU cycles and reduce memory footprint.

`EN_MESSAGE`

File: `os_config.h`

Enables the inter-task messaging system (mailboxes/queues) within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel allocates memory and initializes structures for message passing. Disabling this (0) reduces the static RAM footprint and code size significantly. This flag is a prerequisite for using any OS_Send or OS_Receive functions; if disabled, calling these functions will result in a compile-time error or a kernel panic.

Uso:
Enable this flag when your application requires tasks to exchange data or synchronize via messages. Disable it only in extremely memory-constrained systems where tasks operate in complete isolation to save precious SRAM and Flash space.

`EN_MODBUS_SERVICE`

File: `os_config.h`

Enables or disables the integrated Modbus RTU/TCP communication service within the caOS kernel.

Valore: `1`

Note:
When set to 1, the RTOS allocates memory for the Modbus task and initializes the protocol stack. When set to 0, the service is excluded from the build, reducing Flash and RAM usage. This flag depends on the hardware abstraction layer (HAL) having the necessary UART or Ethernet drivers configured.

Uso:
Set to 1 if your application requires Modbus communication for industrial sensors or PLC integration. Set to 0 to save system resources if the project does not use Modbus. Ensure that the associated communication peripheral is not being used by another task if this flag is enabled to avoid resource conflicts.

`EN_MQTT_SERVICE`

File: `os_config.h`

Enables or disables the integrated MQTT client service within the caOS RTOS stack.

Valore: `1`

Note:
When set to 1, the MQTT task and associated network buffers are initialized during system boot. Disabling this (0) reduces the overall RAM footprint and flash usage by excluding the MQTT protocol stack. This flag depends on the network stack being enabled (e.g., EN_LWIP_STACK must be 1).

Uso:
Set to 1 if your application requires remote telemetry or cloud connectivity via MQTT. Set to 0 if the device operates in a standalone mode or uses a different communication protocol to save system resources. Ensure your heap size is sufficient before enabling, as the MQTT client requires dynamic memory allocation for message buffers.

`EN_NET`

File: `os_config.h`

Enables the integrated networking stack and TCP/IP protocol support within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the kernel initializes the network interface drivers and allocates memory for the socket buffer pool. This flag depends on the hardware abstraction layer (HAL) having Ethernet or Wi-Fi peripherals configured. If set to 0, all network-related tasks and memory allocations are excluded from the build, reducing the total flash and RAM footprint.

Uso:
Enable this flag when your application requires network connectivity (e.g., MQTT, HTTP, or socket communication). Disable it for low-power or resource-constrained applications that do not require connectivity to save memory. Ensure that the network buffer size is also configured in the corresponding header file if this flag is enabled, otherwise, the system may trigger a hard fault during initialization.

`EN_NET_DHCP`

File: `os_config.h`

Enables the Dynamic Host Configuration Protocol (DHCP) client module for automatic IP address assignment.

Valore: `1`

Note:
When set to 1, the RTOS stack attempts to negotiate network settings with a DHCP server upon initialization. If set to 0, the system defaults to a static IP configuration defined in the network settings. This flag requires the TCP/IP stack (e.g., LwIP) to be enabled in the project configuration.

Uso:
Enable this when the device needs to connect to networks where IP addresses are managed by a router or server. Disable it for industrial or point-to-point applications where a fixed, predictable IP address is required to prevent connection delays during boot-up.

`EN_NET_DNS`

File: `os_config.h`

Enables or disables the Domain Name System (DNS) client functionality within the caOS networking stack.

Valore: `1`

Note:
When set to 1, the system includes code to resolve human-readable hostnames (e.g., 'example.com') into IP addresses. When set to 0, the DNS client is excluded from the build, reducing flash memory usage. This flag depends on the TCP/IP stack being enabled; if the network stack is disabled, this flag must also be 0.

Uso:
Enable this (1) if your application needs to connect to remote servers using URLs instead of hardcoded IP addresses. Disable it (0) to save memory if your device only communicates via static IP addresses or if you are performing manual IP resolution.

`EN_NET_FILTER`

File: `os_config.h`

Enables hardware-level packet filtering for network traffic

Valore: `1`

Note:
When set to 1, incoming network packets are filtered at hardware level before reaching the OS network stack, reducing CPU overhead. When set to 0, all packets bypass hardware filtering and go directly to software processing. This flag requires the network hardware to support filtering and depends on proper MAC address configuration. Hardware filtering is typically only available on certain STM32 Ethernet peripherals.

Uso:
Set to 1 when implementing security policies or reducing network processing overhead in production systems. Set to 0 for debugging network issues or when hardware doesn't support filtering. Warning: Setting to 1 on unsupported hardware may cause network initialization failures or packet loss. Only enable if your STM32 device has hardware filtering capabilities.

`EN_NET_MDNS`

File: `os_config.h`

Enables or disables the multicast DNS (mDNS) service discovery protocol within the caOS network stack.

Valore: `1`

Note:
When set to 1, the system announces its hostname and services on the local network, allowing other devices to resolve its IP address via 'hostname.local'. Disabling this (0) reduces memory footprint and CPU overhead by removing the mDNS responder task and associated UDP socket handling. This flag requires the TCP/IP stack to be initialized and typically depends on the EN_NET_UDP flag being enabled.

Uso:
Enable this when you want your device to be discoverable by other network clients without needing a static IP or a central DNS server. Disable it in resource-constrained applications where network discovery is not required or to minimize the attack surface of the device on the local network.

`EN_NET_NTP`

File: `os_config.h`

Enables or disables the Network Time Protocol (NTP) client service within the caOS RTOS stack.

Valore: `1`

Note:
When set to 1, the system initializes the NTP client task to synchronize the internal RTC with external time servers. This flag depends on the network stack being active (EN_NET_STACK must be 1). If disabled, the system will not attempt to fetch network time, and the RTC will rely solely on manual setting or hardware battery backup.

Uso:
Enable this when your application requires accurate, synchronized timestamps for logging or scheduling. Change to 0 if your device operates in an isolated network or if you want to reduce memory footprint and network traffic. Warning: Ensure your network gateway and DNS settings are correctly configured before enabling, otherwise the task may hang waiting for a response.

`EN_NET_SYSLOG`

File: `os_config.h`

Enables or disables the system-wide logging of network events to a remote syslog server.

Valore: `1`

Note:
When set to 1, the RTOS will forward internal network stack events and error messages to a configured UDP syslog server. This feature requires the network stack (TCP/IP) to be initialized and active. Disabling this (0) reduces CPU overhead and memory usage by removing the logging task and buffer allocations.

Uso:
Enable this during the development and debugging phase to monitor network connectivity issues or stack errors in real-time. Disable it in production builds to save system resources and prevent unnecessary network traffic. Ensure the syslog server IP is correctly configured in the network settings before enabling this flag.

`EN_NOTIFY`

File: `os_config.h`

Enables the Task Notification feature, allowing tasks to send lightweight signals or data directly to other tasks.

Valore: `1`

Note:
When set to 1, the OS allocates a notification value and state variable for every task control block. This increases RAM usage per task. It is a prerequisite for using functions like os_task_notify() and os_task_wait_notify(). If set to 0, these functions will be disabled, and the kernel will ignore any notification-related calls.

Uso:
Enable this when you need a fast, low-overhead alternative to semaphores or queues for simple task synchronization or event signaling. Change this to 0 only if you are extremely constrained on RAM and are certain your application does not require direct task-to-task signaling.

`EN_NTP_SERVICE`

File: `os_config.h`

Enables or disables the built-in Network Time Protocol (NTP) client service for automatic system clock synchronization.

Valore: `1`

Note:
When set to 1, the RTOS initializes a background task to periodically query a time server; when set to 0, the service is excluded from the build, reducing flash and RAM usage. This flag requires the TCP/IP stack (e.g., LwIP) to be enabled and a valid network interface to be active.

Uso:
Enable this when your application requires accurate UTC timestamps or logging with real-world time. Disable it if your device operates in an isolated network without internet access or if you are using an external Hardware Real-Time Clock (RTC) module to save system resources.

`EN_PACKET_TRACER`

File: `os_config.h`

Enables the internal diagnostic logging system for tracking inter-task communication packets.

Valore: `1`

Note:
When set to 1, the kernel records metadata for every message queue and mailbox transaction. Enabling this increases CPU overhead and RAM usage for the trace buffer. It depends on the OS_DEBUG_LEVEL being set to at least 1. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag during the development and debugging phase to trace message flow and identify race conditions or lost packets. Disable it in production builds to save memory and improve system performance, as the tracing mechanism consumes significant clock cycles.

`EN_POOL`

File: `os_config.h`

Enables the dynamic memory pool management system within caOS.

Valore: `1`

Note:
When set to 1, the kernel allocates memory from pre-defined fixed-size pools instead of using the standard heap. This prevents memory fragmentation and ensures deterministic allocation times. Disabling this (0) forces the system to rely on standard heap allocation, which may be slower and prone to fragmentation. This flag must be enabled if your application uses message queues or dynamic task creation.

Uso:
Enable this flag when your application requires frequent creation and deletion of objects like tasks or messages. Change this to 0 only if your system is strictly static and you need to save the small amount of RAM overhead required for the pool management structures. Ensure that

the pool sizes defined in the configuration are sufficient for your peak load to avoid allocation failures.

`EN_PWR`

File: `os_config.h`

Enables the power management module for the caOS RTOS.

Valore: `1`

Note:
When set to 1, the kernel enters low-power sleep modes during idle time. When set to 0, the CPU remains in active mode continuously. This flag requires the hardware abstraction layer (HAL) to have tickless idle support configured. Typical values are 0 for debugging and 1 for battery-powered applications.

Uso:
Enable this flag when your device needs to minimize power consumption during periods of inactivity. Disable it if you experience issues with peripheral wake-up latency or if you are using a debugger that loses connection when the CPU enters sleep mode.

`EN_PWR_DBG`

File: `os_config.h`

Enables or disables the power management debug logging features within the RTOS kernel.

Valore: `0`

Note:
When set to 1, the system outputs detailed power state transitions and sleep mode entry/exit logs to the debug console. Disabling it (0) reduces CPU overhead and memory footprint. This flag depends on the global debug logging system being active; if the main logging module is disabled, this flag has no effect.

Uso:
Set to 1 during the development phase when troubleshooting battery life issues or unexpected wake-up events. Set to 0 for production builds to minimize power consumption and prevent UART/ITM buffer overflows caused by excessive logging.

`EN_QSPI`

File: `os_config.h`

Enables or disables the Quad-SPI (QSPI) peripheral driver support within the caOS kernel.

Valore: `0`

Note:
When set to 1, the OS initializes the QSPI controller and includes the necessary HAL drivers for external flash memory access. When set to 0, the QSPI peripheral is ignored, reducing the kernel binary size and freeing up memory. This flag must be enabled if your hardware design uses an external QSPI flash chip for data storage or XIP (Execute-in-Place) operations.

Uso:

Set this to 1 only if your specific STM32 board has an external QSPI flash memory connected. If you attempt to use QSPI functions while this is set to 0, the system will trigger a hard fault or return null pointers. Keep it at 0 for projects that do not require external memory to save precious RAM and Flash resources.

`EN_RNG`

File: `os_config.h`

Enables the hardware random number generator (RNG) peripheral driver within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel initializes the STM32 RNG peripheral and provides a thread-safe API for entropy generation. Disabling this (0) reduces the memory footprint and removes the dependency on the RNG hardware clock. This flag requires the STM32 RNG peripheral to be present on the specific MCU model.

Uso:
Enable this when your application requires cryptographically secure random numbers, unique session IDs, or jitter for network protocols. Change to 0 if you need to save power or if the RNG peripheral is not available on your target hardware. Warning: Ensure the RNG clock is enabled in the system clock configuration, otherwise the kernel may hang during initialization.

`EN_ROUTE_SERVICE`

File: `os_config.h`

Enables the internal routing service for inter-task communication and message passing.

Valore: `1`

Note:
When set to 1, the kernel initializes the routing table and message buffers. Disabling this (0) reduces RAM usage by approximately 2KB but prevents tasks from using the OS_Route_Send() and OS_Route_Receive() APIs. This flag must be enabled if any system modules rely on asynchronous event signaling.

Uso:
Enable this flag when your application requires decoupled communication between tasks. Disable it only in extremely memory-constrained systems where all task synchronization is handled strictly via binary semaphores or direct task notifications to save stack and heap space.

`EN_RTC`

File: `os_config.h`

Enables the Real-Time Clock (RTC) driver integration within the caOS kernel.

Valore: `1`

Note:

When set to 1, the OS initializes the hardware RTC peripheral and provides system-wide timekeeping services. If set to 0, all RTC-related API calls will return an error or remain unimplemented. This flag depends on the underlying STM32 HAL RTC configuration being correctly defined in the project's hardware abstraction layer.

Uso:
Set to 1 if your application requires timestamping, scheduling based on wall-clock time, or low-power wake-up alarms. Disable it (0) to save flash memory and reduce initialization time if the application does not require time-tracking features.

`EN_RWLOCK`

File: `os_config.h`

Enables or disables the Read-Write Lock (RWLock) synchronization primitive in the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel includes code for RWLock objects, allowing multiple readers or a single writer to access a resource. Disabling this (0) reduces the kernel binary size and memory footprint. This flag has no dependencies on other synchronization primitives but is required if any application task attempts to initialize or use an RWLock handle.

Uso:
Enable this flag when your application requires high-concurrency access to shared resources where read operations significantly outnumber write operations. Change to 0 if your project is memory-constrained and does not utilize RWLocks to save flash and RAM. Warning: disabling this while the application code still references RWLock functions will result in compilation errors.

`EN_SAI`

File: `os_config.h`

Enables the Serial Audio Interface (SAI) peripheral driver support in caOS.

Valore: `1`

Note:
When set to 1, the caOS SAI driver module is compiled and initialized, allowing the use of ca_sai_* API functions. This flag consumes additional flash memory and requires the corresponding hardware peripheral to be available on the STM32 chip. If set to 0, any attempt to call ca_sai_* functions will result in a compilation error or linker failure.

Uso:
Enable this flag only when your application requires digital audio streaming (e.g., I2S, TDM, or PDM audio interfaces). If your project does not use audio peripherals, keep this set to 0 to save system resources and reduce the binary footprint.

`EN_SDIO`

File: `os_config.h`

Enables the SDIO peripheral driver for SD card communication within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the OS initializes the SDIO hardware abstraction layer and includes the SD card file system support. Disabling this (0) reduces the binary footprint and frees up CPU cycles if no SD card is used. This flag depends on the hardware having an SDIO interface connected; if enabled without physical hardware, the system may hang during the initialization phase.

Uso:
Set this to 1 when your application requires logging data to an SD card or loading configuration files from external storage. Change to 0 if you are using a different storage medium (like SPI Flash) or if the SDIO pins are needed for other GPIO functions to prevent hardware conflicts.

`EN_SHA256`

File: `os_config.h`

Enables the SHA-256 cryptographic hash function implementation in the RTOS kernel

Valore: `1`

Note:
When set to 1, the RTOS includes SHA-256 hashing capabilities which increases binary size by approximately 2-4KB and requires cryptographic hardware support on STM32 devices. Setting to 0 removes all SHA-256 functionality and will cause linker errors if any application code attempts to use these functions. The flag depends on EN_CRYPTO being enabled for hardware acceleration support.

Uso:
Enable this flag when implementing secure communication protocols, firmware verification, or digital signature validation. Disable only when memory constraints are critical and no cryptographic hashing is required. Warning: Disabling this flag while code references SHA-256 functions will cause compilation failures

---

`EN_SHA256_TEST`

File: `os_config.h`

Enables or disables the built-in SHA-256 cryptographic integrity verification suite for system binaries.

Valore: `1`

Note:
When set to 1, the RTOS performs a checksum validation of the application image during the boot sequence. This requires the hardware CRC or cryptographic acceleration unit to be initialized. If set to 0, the boot time is reduced, but the system loses the ability to detect unauthorized firmware modifications or memory corruption at startup.

Uso:

Enable this flag during production builds to ensure firmware authenticity and integrity. Disable it only during early development stages if you need to speed up the flashing and boot cycle, or if you are using a custom bootloader that handles verification externally. Ensure that your linker script reserves space for the checksum signature if this is enabled.

`EN_SHA512`

File: `os_config.h`

Enables or disables the hardware-accelerated SHA-512 cryptographic hashing module within the RTOS kernel.

Valore: `1`

Note:
When set to 1, the kernel includes SHA-512 support, increasing the binary size and memory footprint. It requires the underlying STM32 hardware to have a functional HASH peripheral. If set to 0, any calls to SHA-512 functions will return an error or trigger a linker error if the code is not wrapped in preprocessor checks.

Uso:
Enable this flag only if your application requires secure hashing, data integrity checks, or digital signature verification. Disable it to save flash memory and RAM if your project does not utilize SHA-512, as it consumes significant system resources.

`EN_SHA512_TEST`

File: `os_config.h`

Enables the built-in SHA-512 cryptographic integrity verification test suite during system startup.

Valore: `1`

Note:
When set to 1, the RTOS executes a self-test routine on the SHA-512 hardware accelerator or software library before the scheduler starts. If set to 0, the test is skipped, reducing boot time. This flag depends on the availability of the cryptographic module in the current STM32 target and requires sufficient stack space for the test execution.

Uso:
Enable this during the development and production validation phases to ensure the integrity of the hashing engine. Disable it only in final production builds if boot time requirements are extremely strict and the hardware has been verified to be reliable across all units.

`EN_SPDIFRX`

File: `os_config.h`

Enables or disables the SPDIFRX peripheral driver support in caOS.

Valore: `0`

Note:
When set to 1, the caOS SPDIFRX driver (ca_spdifrx_*) is compiled into the binary, allowing the application to interface with the hardware SPDIF receiver. When set to 0, the driver is

excluded, reducing flash memory usage. This flag does not have direct dependencies on other peripherals but requires the target STM32 MCU to have a physical SPDIFRX peripheral.

Uso:
Set this to 1 only if your application needs to receive digital audio data via the SPDIF interface. If your project does not use SPDIFRX, keep it at 0 to save code space and avoid unnecessary peripheral initialization code.

`EN_SPI`

File: `os_config.h`

Enables or disables the SPI peripheral driver support within the caOS RTOS kernel.

Valore: `0`

Note:
When set to 1, the system initializes SPI hardware abstraction layers and allocates memory for SPI-related structures. When set to 0, all SPI-related code is excluded from the build, reducing the final binary size. This flag is a prerequisite for any SPI-based communication tasks; if disabled, calls to SPI functions will result in compilation errors or undefined behavior.

Uso:
Set this to 1 only if your application requires SPI communication (e.g., interfacing with sensors, displays, or external memory). Keep it at 0 if your project does not use SPI to save flash memory and RAM. Ensure that the corresponding hardware pins are correctly configured in your STM32CubeMX project if you enable this flag.

`EN_SPI_DMA`

File: `os_config.h`

Enables Direct Memory Access (DMA) support for SPI peripheral communication.

Valore: `1`

Note:
When set to 1, SPI data transfers bypass the CPU, reducing overhead. When set to 0, the system uses standard interrupt-driven or polling methods. This flag requires the corresponding DMA controller clock to be enabled in the system initialization code. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this when your application requires high-speed SPI data transfers or when the CPU is heavily loaded with other tasks. Change to 0 only if you are debugging SPI timing issues or if the specific STM32 hardware configuration lacks DMA support for the chosen SPI instance.

`EN_SSH_SERVICE`

File: `os_config.h`

Enables or disables the integrated SSH server service within the caOS RTOS kernel.

Valore: `1`

Note:

When set to 1, the SSH service task is initialized during system boot, consuming additional RAM for the stack and heap. It requires the TCP/IP stack (e.g., lwIP) to be enabled and configured. If set to 0, the service is excluded from the build, reducing the binary size and freeing up system resources.

Uso:
Enable this flag when remote secure shell access is required for debugging, configuration, or file management over Ethernet. Disable it in production environments where security is a concern or when memory constraints are critical. Ensure that the network interface is properly initialized before enabling this service to prevent boot-time crashes.

`EN_SSH_TEST`

File: `os_config.h`

Enables the Secure Shell (SSH) diagnostic interface for remote system debugging.

Valore: `1`

Note:
When set to 1, the RTOS initializes the SSH server task and binds it to the configured network interface. This flag depends on the network stack being enabled (e.g., LWIP_ENABLED). Disabling this (0) saves significant RAM and CPU cycles by removing the SSH daemon and associated encryption buffers.

Uso:
Enable this during the development and integration phase to allow remote access to the system shell for monitoring and troubleshooting. Disable it in production builds to reduce the attack surface and free up memory resources. Ensure that the network stack is fully initialized before this flag is set to 1 to prevent system crashes during boot.

`EN_SSH_TRACE`

File: `os_config.h`

Enables the Secure Shell (SSH) diagnostic tracing mechanism for remote system monitoring.

Valore: `1`

Note:
When set to 1, the RTOS routes kernel diagnostic logs to the SSH interface. Disabling this (0) reduces CPU overhead and memory usage. This flag depends on the network stack being initialized and requires the SSH_PORT configuration to be defined.

Uso:
Enable this during development or field debugging to monitor task states and system health remotely. Disable it in production builds to save flash memory and prevent potential security vulnerabilities associated with exposed diagnostic ports.

`EN_STLINK_WAIT_READY`

File: `os_config.h`

Enables a mandatory delay during system startup to allow the ST-LINK debugger to initialize and attach.

Valore: `1`

Note:
When set to 1, the system executes a blocking wait loop at the very beginning of main() before the RTOS scheduler starts. If set to 0, the system boots immediately. This flag is independent of other RTOS features but is critical for debugging early-boot code. Typical values are 1 (enabled) for development and 0 (disabled) for production firmware.

Uso:
Enable this (1) if you are experiencing hard faults or erratic behavior immediately after power-on or reset while a debugger is connected. It ensures the IDE has time to halt the CPU before the application code runs. Disable this (0) for final production builds to ensure the device starts up instantly without unnecessary delays.

`EN_STREAM`

File: `os_config.h`

Enables the internal stream processing module for asynchronous data handling.

Valore: `1`

Note:
When set to 1, the kernel allocates memory for stream buffers and enables stream-related API functions. Disabling this (0) reduces the kernel's static RAM footprint. This flag is a prerequisite for using the caOS communication drivers and must be enabled if any peripheral stream tasks are defined in the project.

Uso:
Enable this flag when your application requires non-blocking data transmission or reception via UART, SPI, or I2C. If your project does not use streaming features, keep it disabled to save memory. Ensure that the heap size is sufficient to accommodate the buffers created when this flag is active.

`EN_SW_TIMER`

File: `os_config.h`

Enables the software timer management module within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel initializes the software timer service, allowing tasks to schedule callbacks without hardware timer constraints. Disabling this (0) reduces the kernel's RAM footprint and CPU overhead. This flag must be enabled if any application-level timers or periodic software tasks are utilized.

Uso:
Enable this flag when your application requires non-blocking delays or periodic execution of functions that do not justify a dedicated hardware timer. If you disable this, ensure no part of your code calls timer-related API functions, as this will lead to linker errors or runtime crashes.

`EN_SYSLOG_SERVICE`

File: `os_config.h`

Enables or disables the internal system logging service for debugging and event tracking.

Valore: `1`

Note:
When set to 1, the RTOS records system events to a circular buffer or UART output. Disabling it (0) reduces CPU overhead and saves RAM by removing the logging task and buffer allocation. This flag depends on the availability of a configured output peripheral, such as UART or ITM.

Uso:
Enable this during the development and integration phase to monitor task switching, error codes, and system health. Disable it in production builds to optimize performance and reduce power consumption. Ensure your logging output peripheral is initialized before the scheduler starts if this is enabled.

`EN_TAMP`

File: `os_config.h`

Enables or disables the hardware tamper detection feature for the system.

Valore: `0`

Note:
When set to 1, the system initializes and monitors hardware tamper pins (via ca_exti_tamper_enable). When set to 0, this functionality is disabled, saving memory and CPU cycles. This flag depends on the underlying STM32 hardware support for tamper detection. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Change this value to 1 if your application requires physical security, such as detecting chassis intrusion or unauthorized access to the board. If your hardware design does not include tamper switches or if you do not need this security feature, keep it at 0 to avoid unnecessary interrupt overhead and potential false triggers.

`EN_TCP_SERVICE`

File: `os_config.h`

Enables or disables the integrated TCP/IP networking stack service within the caOS kernel.

Valore: `1`

Note:
When set to 1, the RTOS initializes the TCP/IP stack and allocates necessary memory buffers for network communication. When set to 0, the stack is excluded from the build, reducing flash and RAM usage. This flag requires the hardware abstraction layer (HAL) for the Ethernet or Wi-Fi peripheral to be correctly configured in the project.

Uso:
Set to 1 if your application requires network connectivity (e.g., web server, MQTT, or socket communication). Set to 0 if the device is standalone to save system resources. Warning: Disabling this will cause compilation errors if your application code contains calls to network-related APIs.

EN_TCP_TRACE

File: `os_config.h`

Enables or disables the internal diagnostic logging for the TCP/IP stack.

Valore: `0`

Note:
When set to 1, the system outputs detailed packet processing and connection state logs to the debug console. When set to 0, tracing is disabled, reducing CPU overhead and memory usage. This flag depends on the underlying UART or ITM debug interface being initialized.

Uso:
Set to 1 only during development or when troubleshooting network connectivity issues. Always set to 0 in production builds to prevent performance degradation and excessive log data flooding the serial port.

EN_TFTP_SERVICE

File: `os_config.h`

Enables or disables the built-in Trivial File Transfer Protocol (TFTP) server service within the RTOS.

Valore: `1`

Note:
When set to 1, the system initializes the TFTP stack and binds it to the network interface. This requires the TCP/IP stack (e.g., LwIP) to be enabled and configured. Disabling this (0) reduces the memory footprint and removes the network port dependency.

Uso:
Enable this flag when you need to perform remote firmware updates or configuration file transfers over Ethernet. Ensure that the network stack is fully initialized before this service starts; setting this to 1 without a valid network interface configuration may cause the system to hang during the boot sequence.

EN_TIMER

File: `os_config.h`

Enables the internal software timer management system within the caOS kernel.

Valore: `1`

Note:
When set to 1, the kernel initializes the timer task and processes software timer callbacks. If set to 0, all software timer functionality is disabled, reducing RAM and CPU overhead. This flag is a prerequisite for using any os_timer_create or os_timer_start functions. It requires a defined OS_TIMER_TASK_PRIORITY and OS_TIMER_STACK_SIZE in the configuration file.

Uso:
Enable this flag when your application requires periodic tasks or delayed execution events. Disable it if your system is strictly event-driven or resource-constrained to save memory. Warning:

Disabling this while application code attempts to start a timer will result in a kernel assertion or undefined behavior.

`EN_TLS`

File: `os_config.h`

Enables or disables the Transport Layer Security (TLS) stack support within the caOS RTOS.

Valore: `1`

Note:
When set to 1, the system includes the code and memory structures required for TLS communication (e.g., ca_tls_* functions). Disabling this (set to 0) reduces the firmware binary size and RAM usage by excluding cryptographic overhead. This flag is a prerequisite for using secure network services like HTTPS or secure MQTT.

Uso:
Enable this flag when your application needs to establish encrypted network connections. If your project does not require secure communication, set this to 0 to save significant flash and heap memory. Ensure that your hardware has sufficient resources, as TLS operations are computationally intensive and require additional memory buffers.

`EN_UART_DMA`

File: `os_config.h`

Enables or disables Direct Memory Access (DMA) support for UART communication peripherals.

Valore: `0`

Note:
When set to 1, UART data transfers are offloaded to the DMA controller, reducing CPU overhead. When set to 0, the system uses standard interrupt-driven or polling-based I/O. Enabling this requires proper DMA stream/channel configuration in the STM32 CubeMX or hardware abstraction layer. It is typically a boolean flag (0 or 1).

Uso:
Set to 1 if your application handles high-speed serial communication or requires low CPU utilization during data transmission. Set to 0 if you are debugging UART issues, have limited DMA resources, or if the application has very low throughput requirements where the overhead of DMA setup is not justified.

`EN_UDP_CLIENT`

File: `os_config.h`

Enables or disables the UDP client functionality within the caOS networking stack.

Valore: `0`

Note:

When set to 1, the system allocates memory buffers and initializes the UDP socket interface. When set to 0, the UDP client code is excluded from the build, reducing the overall flash memory footprint. This flag depends on the global network stack being enabled in the configuration.

Uso:
Set this to 1 only if your application needs to send or receive data via UDP protocols. If your project only uses TCP or does not require network communication, keep this at 0 to save system resources and avoid unnecessary memory allocation.

`EN_UDP_SERVER`

File: `os_config.h`

Enables or disables the built-in UDP server functionality within the caOS network stack.

Valore: `1`

Note:
When set to 1, the RTOS initializes the UDP socket listener and allocates memory for the UDP buffer. If set to 0, the UDP server code is excluded from the build, reducing flash memory usage. This flag depends on the network stack being enabled in the project configuration.

Uso:
Set to 1 if your application needs to receive or send data via UDP packets. Set to 0 if your device only uses TCP or does not require network communication to save system resources. Ensure that the UDP buffer size is also configured correctly if this flag is enabled.

`EN_USB`

File: `os_config.h`

Enables the USB stack and hardware peripheral drivers within the caOS RTOS environment.

Valore: `1`

Note:
When set to 1, the kernel initializes USB-related memory pools and interrupt handlers. Disabling this (0) reduces the binary footprint and frees up RAM. This flag depends on the hardware abstraction layer (HAL) being configured for USB support in the STM32 CubeMX project.

Uso:
Set to 1 when your application requires USB communication (e.g., Virtual COM Port, HID, or Mass Storage). Disable it if your project does not use USB to save system resources and avoid potential conflicts with USB interrupt vectors.

`EN_USB_CDC`

File: `os_config.h`

Enables or disables the USB Communications Device Class (CDC) driver stack within the RTOS.

Valore: `0`

Note:

When set to 1, the system initializes the USB peripheral and allocates memory for the CDC buffer and interrupt handlers. When set to 0, the USB stack is completely excluded from the build, reducing flash and RAM usage. This flag depends on the hardware having a USB-capable STM32 peripheral and requires the USB clock configuration to be active in the system clock tree.

Uso:
Set to 1 if your application requires a virtual COM port for logging, debugging, or data communication with a PC. Set to 0 if the USB peripheral is not used or if you need to save memory resources. Ensure that if this is enabled, the corresponding USB interrupt priority is correctly configured in the NVIC to avoid blocking the RTOS scheduler.

`EN_USB_CUSTOM`

File: `os_config.h`

Enables or disables the custom USB stack implementation within the caOS RTOS.

Valore: `0`

Note:
When set to 1, the system uses the custom caOS USB driver; when set to 0, the system defaults to the standard STM32 HAL USB library. This flag requires the USB peripheral clock to be configured in the system clock tree. Disabling this (0) is recommended for standard HID or CDC applications to ensure compatibility with ST-provided drivers.

Uso:
Change this to 1 only if you are implementing a proprietary USB class or require low-level control over USB descriptors not supported by the standard HAL. Keep this at 0 for most projects to avoid unnecessary code bloat and potential stability issues with standard USB host controllers.

`EN_USB_DBG`

File: `os_config.h`

Enables or disables the USB-based debug interface for the caOS RTOS.

Valore: `0`

Note:
When set to 1, the system initializes the USB peripheral to stream debug logs and telemetry to a host PC. When set to 0, the USB peripheral is disabled, saving CPU cycles and memory. This flag requires the hardware USB pins to be correctly configured in the board support package (BSP).

Uso:
Set to 1 during development to monitor system state and task execution via a serial terminal. Set to 0 for production builds to reduce power consumption and prevent unauthorized access to system logs. Ensure the USB clock is configured in the system clock tree before enabling this flag.

`EN_USB_DFU`

File: `os_config.h`

Enables or disables the USB Device Firmware Upgrade (DFU) bootloader functionality within the RTOS.

Valore: `0`

Note:
When set to 1, the system initializes the USB DFU stack, allowing firmware updates over USB. When set to 0, this feature is disabled, saving flash memory and RAM. This flag requires the USB hardware peripheral to be physically connected and configured in the hardware abstraction layer.

Uso:
Set to 1 during the production phase or when field updates are required. Set to 0 during standard development to save resources or if the USB interface is not used. Warning: Disabling this while the device is in the field will prevent remote firmware updates via USB.

`EN_USB_FS`

File: `os_config.h`

Enables the Full-Speed USB peripheral driver within the caOS RTOS stack.

Valore: `1`

Note:
When set to 1, the RTOS initializes the USB hardware abstraction layer and allocates memory for USB buffers. This flag depends on the hardware having a physical USB FS controller (e.g., STM32F103 or STM32F407). If set to 0, all USB-related tasks and interrupt service routines are excluded from the build, reducing the binary footprint.

Uso:
Set this to 1 when your application requires USB communication (CDC, HID, or MSC). You must ensure that the system clock is configured to 48MHz for the USB peripheral to function correctly. Disable this flag if you are not using USB to save RAM and Flash memory, or if you are using a different communication interface like UART or CAN.

`EN_USB_HS`

File: `os_config.h`

Enables or disables the High-Speed (HS) USB peripheral controller driver in the caOS kernel.

Valore: `0`

Note:
When set to 1, the kernel initializes the USB HS hardware abstraction layer and allocates memory for its associated buffers. When set to 0, the peripheral is disabled, saving RAM and flash memory. This flag depends on the hardware having an external ULPI PHY or an integrated HS PHY. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Set this to 1 only if your specific STM32 board design includes a High-Speed USB PHY and you intend to use USB 2.0 HS communication. If you are using Full-Speed (FS) USB or no USB

at all, keep this at 0 to prevent hard faults caused by accessing uninitialized or non-existent hardware registers.

`EN_USB_MSC`

File: `os_config.h`

Enables or disables the USB Mass Storage Class (MSC) driver stack within the RTOS.

Valore: `0`

Note:
When set to 1, the system initializes the USB peripheral as a storage device (like a flash drive). When set to 0, the USB MSC stack is excluded from the build, reducing flash memory usage and disabling USB storage functionality. This flag depends on the hardware having a USB-capable STM32 peripheral and requires the USB hardware abstraction layer (HAL) to be configured.

Uso:
Set this to 1 if your application needs to expose internal memory or an SD card as a drive to a PC. Set to 0 if you are not using USB storage to save code space and avoid unnecessary interrupt overhead. Ensure that the system clock is configured for USB operation (48MHz) before enabling this flag.

`EN_USB_NCM`

File: `os_config.h`

Enables the Network Control Model (NCM) class support for the USB stack.

Valore: `1`

Note:
When set to 1, the RTOS initializes the USB NCM driver, allowing the device to appear as a virtual Ethernet adapter over USB. This requires the USB peripheral to be configured in Device mode and depends on the underlying USB hardware abstraction layer (HAL) being active. Disabling this (0) removes the NCM stack from the build, reducing flash memory usage. The NCM implementation requires additional RAM for USB buffer management and will increase the overall memory footprint of the application.

Uso:
Enable this flag when you need to implement USB-to-Ethernet bridging or RNDIS-like connectivity for network debugging. Change this value only if your application requires USB networking; ensure that the USB clock and GPIO pins are correctly initialized in your board support package before enabling. Warning: Do not enable this flag if your USB peripheral is not properly configured for device mode, as it will cause runtime errors. Typical use cases include firmware update over USB, network monitoring, and remote debugging scenarios.

`EN_WDT`

File: `os_config.h`

Enables the internal Watchdog Timer (WDT) supervisor for the caOS kernel.

Valore: `1`

Note:

When set to 1, the kernel periodically resets the hardware watchdog timer. If the system hangs or enters an infinite loop, the WDT will trigger a hardware reset. This flag depends on the hardware-specific WDT peripheral initialization being completed in the board support package. Typical values are 1 (enabled) or 0 (disabled).

Uso:
Enable this in production builds to ensure system recovery from unexpected software freezes. Disable it only during debugging sessions when using breakpoints, as the WDT will otherwise trigger a reset while the CPU is halted.

`EN_X25519`

File: `os_config.h`

Enables the X25519 Elliptic Curve Diffie-Hellman (ECDH) key exchange algorithm within the caOS cryptographic library.

Valore: `1`

Note:
When set to 1, the system includes the X25519 implementation, increasing the flash memory footprint by approximately 4KB. It requires the hardware random number generator (RNG) peripheral to be initialized. If set to 0, any attempt to call secure handshake functions will result in a compile-time error or a runtime 'feature not supported' exception.

Uso:
Enable this flag when your application requires secure key exchange for encrypted communication (e.g., TLS or custom secure protocols). Disable it if you are strictly optimizing for code space and your project does not perform asymmetric key exchanges. Ensure your STM32 chip has sufficient flash capacity before enabling.

`EN_X25519_TEST`

File: `os_config.h`

Enables the built-in self-test suite for the X25519 elliptic curve cryptography module.

Valore: `1`

Note:
When set to 1, the system executes a series of known-answer tests (KAT) during the kernel initialization phase. If set to 0, these tests are skipped, reducing boot time and flash memory footprint. This flag depends on the presence of the cryptographic library module in the build configuration.

Uso:
Enable this flag during the development and integration phase to verify that the X25519 implementation is functioning correctly on the target STM32 hardware. It is recommended to disable this (set to 0) in production firmware to minimize startup latency and prevent potential security side-channel exposure during the test execution.

`ETH_MPU_REGION`

File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the Memory Protection Unit (MPU) region index reserved for the Ethernet DMA descriptor memory space.

Valori per MCU:

MCU	Valore
F407	5U
F429	5U
F746	5U
H563	5U
H747	5U
H753	5U

Note:
This constant assigns a specific MPU slot (0-7) to the Ethernet peripheral's memory buffers. Enabling this ensures the MPU correctly marks the Ethernet memory as non-cacheable or shareable to prevent data coherency issues. It is strictly dependent on the hardware architecture; all supported STM32 variants currently require index 5. Changing this value without updating the corresponding MPU configuration table will lead to memory access faults or Ethernet driver failure.

Uso:
This value should generally remain at 5U for all supported STM32 targets. You should only modify this if you are porting caOS to a new MCU architecture where region 5 is already occupied by another critical system peripheral or if the hardware memory map requires a different slot allocation to avoid overlapping protection regions.

`ETH_P_ARP`

File: `caos/net/inc/net.h`

The Ethernet protocol identifier for the Address Resolution Protocol (ARP).

Valore: `0x0806U`

Note:
This constant represents the EtherType field value (0x0806) used in Ethernet frames to indicate that the payload contains an ARP packet. It is a fixed standard defined by IEEE 802.3. Changing this value will cause the network stack to ignore all incoming ARP requests and replies, effectively breaking IPv4 address resolution.

Uso:
This value should never be changed in standard network applications. It is used by the caOS network driver to filter incoming Ethernet frames and identify which packets should be passed to the ARP handler. If you are debugging raw Ethernet frames and notice that ARP packets are not being processed, verify that the hardware filter or the driver's receive logic is correctly comparing the incoming EtherType against this constant.

ETH_P_IP

File: `caos/net/inc/net.h`

The Ethernet protocol identifier for the Internet Protocol (IPv4) packet type.

Valore: `0x0800U`

Note:
This constant represents the EtherType field value 0x0800, which signals that the payload of an Ethernet frame is an IPv4 packet. It is a standard value defined by IEEE 802.3. Changing this value will cause the network stack to ignore all incoming IPv4 traffic, as the hardware or driver will fail to match the frame type.

Uso:
This value should generally remain unchanged as it is a fixed networking standard. You would only reference this constant when writing custom packet filters, raw socket handlers, or low-level Ethernet driver logic to identify or construct IPv4 frames. Do not modify this value unless you are implementing a non-standard protocol stack.

ETH_P_IPV6

File: `caos/net/inc/net.h`

Defines the Ethernet protocol identifier for IPv6 packets.

Valore: `0x86DDU`

Note:
This constant represents the EtherType value 0x86DD used in the Ethernet frame header to indicate that the payload is an IPv6 packet. It is a fixed standard defined by IEEE 802.3. Changing this value will cause the network stack to fail to recognize or process any incoming IPv6 traffic, as the hardware/driver will no longer match the frame type correctly.

Uso:
This value should generally never be changed as it is defined by international networking standards. You would only reference this constant when writing custom packet filters, raw socket handlers, or debugging the network stack to verify that the Ethernet layer is correctly identifying IPv6 frames.

ETH_P_VLAN

File: `caos/net/inc/net.h`

Defines the standard IEEE 802.1Q EtherType value used to identify VLAN-tagged Ethernet frames.

Valore: `0x8100U`

Note:
This constant represents the hex value 0x8100, which is the global standard for VLAN tagging. When enabled in the network stack, the system will parse incoming frames for this specific header to extract VLAN IDs. It is a read-only configuration for the protocol parser and should not be modified unless working with non-standard or proprietary network encapsulation.

Uso:

Use this value when configuring the Ethernet MAC filter or the packet inspection layer to ensure the RTOS correctly identifies and strips VLAN tags. Do not change this value for standard network communication, as doing so will cause the stack to ignore all standard VLAN-tagged traffic.

FAT_CRYPT_CHUNK

File: caos/drivers/inc/fat_service.h

Defines the size in bytes of the data buffer used for cryptographic operations within the FAT file system driver.

Valore: 512U

Note:
This constant determines the memory footprint of the encryption/decryption buffer. It must be a multiple of the underlying storage sector size (typically 512 bytes). Increasing this value can improve throughput for large file operations but will consume more RAM from the heap or static pool. It is strictly dependent on the hardware's DMA alignment requirements.

Uso:
Adjust this value if you encounter performance bottlenecks during file I/O or if you need to optimize RAM usage on memory-constrained STM32 devices. Ensure the value is a power of two to maintain compatibility with standard FAT sector alignment. Setting this too low may increase CPU overhead due to frequent context switching during encryption tasks.

HASH_CTX_INIT_CAP

File: caos/drivers/inc/hash.h

Defines the initial memory allocation size in bytes for the hashing context buffer.

Valore: 256U

Note:
This constant determines the static memory footprint of the hash driver's internal state. Increasing this value allows for larger internal buffers or more complex hashing algorithms, while decreasing it saves RAM. It must be large enough to accommodate the context structure of the specific hardware peripheral or software algorithm being used; otherwise, the driver will trigger a buffer overflow or memory corruption.

Uso:
Adjust this value if you encounter memory allocation errors during hash initialization or if you switch to a hashing algorithm that requires a larger state structure. Do not set this value lower than the size of the largest context structure required by your enabled algorithms, as this will lead to undefined behavior or system crashes.

HASH_MAX_DIGEST_SIZE

File: caos/drivers/inc/hash.h

Defines the maximum buffer size in bytes allocated for storing cryptographic hash results.

Valore: 32

Note:

This constant sets the static memory allocation for hash output buffers. If set too low, hashing algorithms requiring larger outputs (like SHA-256) will trigger buffer overflows or truncation errors. It must be at least 32 to support SHA-256. Increasing this value consumes more RAM in the driver's internal state structures.

Uso:
Change this value only if you need to support newer or stronger hashing algorithms that produce digests larger than 32 bytes (e.g., SHA-512). Ensure that all application-level buffers receiving hash outputs are sized according to this constant to prevent memory corruption.

`HASH_SHA1_DIGEST_SIZE`

File: `caos/drivers/inc/hash.h`

Defines the fixed output length in bytes for the SHA-1 cryptographic hash algorithm.

Valore: `20`

Note:
The value is set to 20 bytes (160 bits) as per the SHA-1 standard specification. This constant is used to allocate buffers for hash results. Changing this value will cause the SHA-1 hardware peripheral or software implementation to produce incorrect results or trigger buffer overflows in dependent code.

Uso:
This value should not be changed as it is strictly defined by the SHA-1 algorithm. It is used primarily for static memory allocation in security modules and communication protocols that require SHA-1 integrity checks. If you need a different digest size, you must switch to a different algorithm (e.g., SHA-256) rather than modifying this constant.

`HASH_SHA256_DIGEST_SIZE`

File: `caos/drivers/inc/hash.h`

Defines the fixed output length in bytes for the SHA-256 cryptographic hash algorithm.

Valore: `32`

Note:
This constant is set to 32 bytes (256 bits) as per the SHA-256 standard. Changing this value will break compatibility with standard cryptographic libraries and hardware acceleration drivers. It is a read-only configuration used to allocate buffers for hash results.

Uso:
Do not modify this value unless you are implementing a custom variant of the algorithm. It is used to size arrays that store the final digest; setting it incorrectly will lead to buffer overflows or truncated hash outputs.

`HCLK_FREQ_HZ`

File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`

File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the AHB bus clock frequency (HCLK) in Hertz for the system timer and peripheral timing calculations.

Valori per MCU:

MCU	Valore
F407	168000000UL
F429	168000000UL
F446	168000000UL
F746	216000000UL
H563	250000000UL
H747	200000000UL
H753	240000000UL

Note:
This constant is used by the RTOS kernel to calibrate the system tick timer (SysTick) and ensure accurate task scheduling. If this value does not match the actual hardware clock configuration set in the RCC registers, timing-dependent functions like vTaskDelay() or hardware timeouts will run at the wrong speed. It must be set to the exact frequency resulting from your PLL and prescaler settings.

Uso:
Change this value whenever you modify the system clock tree configuration (e.g., changing the crystal frequency or PLL multipliers). If your tasks are running faster or slower than expected, or if communication peripherals like UART/I2C have baud rate errors, verify that this constant matches the actual HCLK frequency output by the MCU clock tree.

`HKDF_SHA256_MAX_OUT`

File: `caos/crypto/inc/kdf.h`

Defines the maximum output length in bytes for the HKDF-SHA256 key derivation function.

Valore: `(255U * SHA256_DIGEST_SIZE)`

Note:
This constant sets the upper limit for the key material generated by the HKDF process. It is calculated as 255 times the SHA256 digest size (32 bytes), resulting in a maximum of 8160 bytes. Increasing this value consumes more stack or heap memory during the derivation process, while decreasing it limits the amount of key material you can extract in a single call.

Uso:
Modify this value only if your application requires a specific, smaller buffer size to save RAM, or if you need to generate larger amounts of key material than the default allows. Ensure that the buffer passed to ca_hkdf_sha256 does not exceed this limit to prevent buffer overflows.

`HMAC_SHA256_SIZE`

File: `caos/crypto/inc/kdf.h`

Defines the fixed byte length of the HMAC-SHA256 output digest.

Valore: `SHA256_DIGEST_SIZE`

Note:
This constant is set to SHA256_DIGEST_SIZE (32 bytes). It determines the buffer size required for storing HMAC-SHA256 results. Changing this value will break compatibility with standard HMAC-SHA256 implementations and cause buffer overflows or truncated data if the underlying ca_hmac_sha256 functions expect the standard 32-byte output.

Uso:
Do not change this value under normal circumstances. It is used by the ca_hmac_sha256 family of functions to allocate memory for cryptographic operations. If you are implementing a custom protocol that requires a truncated HMAC, perform the truncation manually after the calculation rather than modifying this constant.

`HTTPS_DEFAULT_PORT`

File: `os_config.h`

Defines the default TCP port number used for HTTPS communication services.

Valore: `443U`

Note:
This constant sets the listening or connection port for the ca_https service. The value 443U is the IANA standard for HTTPS. Changing this value will prevent the device from connecting to standard web servers unless they are specifically configured to listen on a non-standard port. It is a 16-bit unsigned integer.

Uso:
Modify this value only if your application must communicate with an HTTPS server running on a non-standard port (e.g., 8443). Do not change this for standard web traffic. Ensure the server side is configured to match this port, otherwise, the connection will be rejected by the remote host.

`HTTP_DEFAULT_PORT`

File: `os_config.h`

Defines the default TCP port number used by the caOS HTTP server when no specific port is provided.

Valore: `80U`

Note:
This constant sets the listening port for the HTTP stack. Changing this value affects all incoming HTTP connections. It must be a valid 16-bit unsigned integer (1-65535). Ensure that the chosen port does not conflict with other network services running on the STM32, such as DHCP or MQTT.

Uso:
Change this value if your application needs to run on a non-standard port (e.g., 8080 for development or 443 for HTTPS). Note that ports below 1024 are typically reserved for system services; using them may require specific network privileges or configurations.

`HTTP_METHOD_GET`

File: `caos/net/inc/http_service.h`

A bitmask flag representing the HTTP GET request method used by the caOS network service.

Valore: `0x01U`

Note:
This constant is used to identify or filter HTTP GET requests within the service stack. It is typically used in conjunction with other method flags (e.g., POST, PUT) as part of a bitwise field. The value 0x01U is a fixed identifier and should not be modified to ensure compatibility with the internal HTTP parser.

Uso:
Use this flag when configuring request handlers or defining allowed methods for a specific endpoint. Do not change this value, as it is hardcoded to match the HTTP protocol specification expected by the caOS network stack. If you are implementing a custom callback, check the incoming request method against this constant using a bitwise AND operation.

`HTTP_METHOD_HEAD`

File: `caos/net/inc/http_service.h`

A constant representing the HTTP HEAD method identifier used by the caOS network stack.

Valore: `0x04U`

Note:
This value is used internally by the HTTP service to identify requests that ask for header information only, without the response body. It must match the value expected by the server-side parser. It is a static identifier and does not affect system memory or task scheduling.

Uso:
Use this constant when implementing custom HTTP request handlers or filtering incoming traffic. Do not modify this value unless you are updating the entire network stack to a different protocol specification, as changing it will cause the HTTP service to fail to recognize HEAD requests.

`HTTP_METHOD_OPTIONS`

File: `caos/net/inc/http_service.h`

A bitmask flag used to enable or disable support for the HTTP OPTIONS method in the caOS web server.

Valore: `0x08U`

Note:
When enabled, the HTTP service will process and respond to OPTIONS requests, typically used for CORS preflight checks. If disabled, the server will return a 405 Method Not Allowed error for these requests. This flag is part of a bitmask configuration; it must be ORed with other method flags (e.g., GET, POST) to define the full set of supported HTTP verbs.

Uso:

Enable this flag if your web application requires CORS support or if a client needs to query the server's capabilities. Disable it to reduce the memory footprint and attack surface if your application only performs simple data retrieval or submission.

HTTP_METHOD_POST

File: caos/net/inc/http_service.h

A constant representing the HTTP POST request method identifier used by the caOS networking stack.

Valore: 0x02U

Note:
This value is used internally by the HTTP service to distinguish POST requests from other methods like GET (0x01) or PUT (0x03). It is typically passed as an argument to the http_send_request function. It has no direct impact on system memory or scheduling, but must match the protocol definition expected by the remote server.

Uso:
Use this constant when you need to send data to a server, such as submitting a form or uploading sensor readings. Do not change this value unless you are modifying the core HTTP protocol implementation, as changing it will cause the server to reject the request or misinterpret the data payload.

HTTP_QUERY_MAX

File: caos/net/inc/http_service.h

Defines the maximum character length allowed for an incoming HTTP query string.

Valore: 128U

Note:
This constant sets the buffer size for parsing URL parameters. If the incoming query exceeds 128 bytes, the HTTP service will truncate the data or return a 414 Request-URI Too Long error. It must be large enough to accommodate your longest expected URL parameters but should be kept small to conserve RAM in the heap or stack.

Uso:
Increase this value if your application requires processing long URL query strings or complex API parameters. Decrease it if you are running low on system memory and your application only uses short, simple query strings. Ensure that the buffer allocated in the HTTP task is sufficient to hold this value plus any necessary headers.

HTTP_RECV_TIMEOUT_MS

File: caos/net/inc/http_service.h

Defines the maximum time in milliseconds the HTTP service waits for incoming data packets before aborting the request.

Valore: 1500U

Note:

Increasing this value allows for slower network connections but consumes more memory and blocks the task for longer periods. Decreasing it improves responsiveness but may cause premature timeouts on high-latency networks. It is dependent on the underlying TCP stack timeout settings and should generally be greater than the round-trip time of the network.

Uso:
Adjust this value if you encounter frequent 'HTTP Timeout' errors during data reception. Increase it if the device is operating on a slow or congested network. Decrease it if you need the system to fail fast to maintain real-time performance. Ensure the value is not set too low, or valid data transfers will be interrupted.

`HTTP_REQ_BUF_SIZE`

File: `os_config.h`

Defines the maximum size in bytes for the internal buffer used to store incoming HTTP request data.

Valore: `2048U`

Note:
Increasing this value allows the system to handle larger HTTP headers or payloads but directly consumes more RAM from the heap. It must be large enough to accommodate the longest expected request header; if the request exceeds this size, the parser will return an error. Typical values range from 512 to 4096 depending on available memory.

Uso:
Increase this value if you encounter 'HTTP 414 Request-URI Too Long' or '400 Bad Request' errors when sending complex requests. Decrease it if the system is running low on heap memory and you are only handling small, simple API calls.

`HTTP_RESP_BUF_SIZE`

File: `os_config.h`

Defines the maximum size in bytes of the buffer used to store incoming HTTP response payloads.

Valore: `4096U`

Note:
This constant allocates a static memory block for HTTP data processing. Increasing this value allows the system to handle larger HTTP responses but directly increases the static RAM footprint of the application. It must be large enough to hold the expected response body; if the response exceeds this size, the HTTP client will truncate the data or return an overflow error. Ensure that the total RAM usage does not exceed the STM32 device's available heap and stack limits.

Uso:
Adjust this value when your application needs to fetch larger JSON objects or files from a web server. If you encounter 'Buffer Overflow' or 'Incomplete Data' errors during HTTP GET requests, increase this value. Conversely, if your device is running low on RAM, decrease this value to the smallest size that still accommodates your largest expected response.

HTTP_URI_MAX

File: caos/net/inc/http_service.h

Defines the maximum character length allowed for an HTTP request URI string.

Valore: 128U

Note:
This constant sets the size of the static buffer used to store incoming URI paths. If the incoming URI exceeds 128 bytes, the HTTP service will return a 414 Request-URI Too Long error. It directly impacts the memory footprint of the HTTP task stack or heap allocation. Valid range is typically 32 to 1024 depending on available RAM.

Uso:
Increase this value if your application requires complex REST API endpoints with long query parameters or deep directory structures. Decrease it to save RAM if your device only handles simple, short resource requests. Ensure the value is large enough to accommodate the longest expected URI plus the null terminator.

I2C_EN_IRQ

File: caos/drivers/inc/i2c.h

Enables interrupt-driven mode for the I2C peripheral driver.

Valore: ((u16)0x0102U)

Note:
When enabled, the driver uses hardware interrupts to handle data transfer instead of blocking the CPU in a polling loop. This requires the corresponding I2C interrupt vector to be enabled in the NVIC. If disabled, the driver defaults to a blocking polling mechanism. The value 0x0102 acts as a bitmask configuration for the I2C peripheral control register.

Uso:
Enable this flag to improve system efficiency and allow the CPU to perform other tasks while waiting for I2C data transfers to complete. Change this to disabled only if you are debugging timing-sensitive issues or if the system lacks sufficient interrupt priority resources. Ensure that the I2C interrupt handler is correctly implemented in your project before enabling this flag to prevent system hangs.

IPERF_DEFAULT_DURATION_MS

File: os_config.h

Defines the default execution time in milliseconds for the built-in iPerf network performance test.

Valore: 10000U

Note:
This constant sets the duration for which the network stack will transmit or receive data during a test session. It is used as the fallback value when no specific duration is provided by the user command. The value must be a positive integer representing milliseconds; typical values range from 1000U to 60000U depending on the desired test granularity.

Uso:

Adjust this value if your network performance tests are too short to provide a stable average or too long, causing system unresponsiveness. Increase this value if you need to observe long-term network stability or throughput trends. Be aware that setting an excessively high value may block other low-priority tasks if the iPerf task is not properly preempted.

`IPERF_DEFAULT_PORT`

File: `os_config.h`

Defines the default TCP/UDP port number used by the caOS built-in iPerf network performance testing utility.

Valore: `5001U`

Note:
This constant sets the listening port for the iPerf server task. It must be a valid 16-bit unsigned integer (1-65535). Changing this value requires a recompile of the firmware. Ensure the chosen port does not conflict with other network services like HTTP (80) or MQTT (1883).

Uso:
Change this value if your network environment or firewall policies restrict the use of port 5001, or if you need to run multiple iPerf instances simultaneously on different ports. Always ensure the client-side testing tool is configured to match this port number, otherwise, the connection will be refused.

`IPERF_IDLE_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum duration in milliseconds the system waits for network activity before entering an idle state during iPerf testing.

Valore: `3000U`

Note:
When enabled, the system monitors incoming packets; if no data is received within this window, the test session is terminated. This value is dependent on the network stack's tick rate. Typical values range from 1000U to 10000U depending on the expected latency of the network environment.

Uso:
Increase this value if you experience premature test termination due to high network jitter or slow link initialization. Decrease it if you need the system to recover faster from dropped connections. Setting this value too low may cause valid tests to fail, while setting it too high may prevent the system from freeing up resources after a genuine connection loss.

`IP_DEFRAG_MAX_PAYLOAD`

File: `os_config.h`

Defines the maximum size in bytes of the reassembled IP packet payload that the system can buffer.

Valore: `1480U`

Note:

This constant sets the memory limit for the IP fragmentation reassembly buffer. If set too low, fragmented packets larger than this value will be dropped. If set too high, it increases static RAM consumption. The value must be a multiple of the MTU and is typically set to 1480 to accommodate standard Ethernet frames minus the IP header.

Uso:
Increase this value if your application receives large fragmented IP packets that are currently being discarded. Decrease it to save RAM if your network environment guarantees that packets will not exceed a smaller size. Ensure the value does not exceed the total available heap or static buffer allocation defined in the network stack configuration.

`IP_DEFRAG_MAX_SESSIONS`

File: `os_config.h`
File: `caos/net/inc/ip_defrag.h`

Defines the maximum number of concurrent IP fragments the system can track for reassembly.

Valore: `8U`

Note:
This constant determines the size of the internal buffer pool for fragmented packets. Increasing this value consumes more RAM but allows the system to handle more simultaneous fragmented network streams. It must be set based on available heap memory and expected network traffic patterns. Typical values range from 4 to 16 depending on the STM32 memory footprint.

Uso:
Increase this value if your application experiences dropped packets or network communication failures when receiving large data frames over UDP or TCP. Decrease it if the system is running low on RAM. Setting this value too high may lead to heap exhaustion, while setting it too low will cause the network stack to discard incoming fragments.

`IP_DEFRAG_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds to wait for all fragments of an IP packet to arrive before discarding them.

Valore: `15000U`

Note:
When enabled, the system buffers incoming IP fragments until the full packet is reassembled or this timer expires. If set too low, fragmented packets will be dropped, causing network communication failures. If set too high, it consumes more system memory by holding incomplete packets longer. Typical values range from 5000 to 30000 depending on network latency.

Uso:
Increase this value if you observe packet loss or incomplete data reception in environments with high network latency or congested links. Decrease it if you are running low on heap memory and need to free up buffers faster. Ensure this value is consistent with the expected round-trip time of your network infrastructure.

`IP_FLAG_DF`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the 'Don't Fragment' (DF) option in the IPv4 header.

Valore: `0x4000U`

Note:
When this bit is set in the IP header flags field, it instructs routers not to fragment the packet. If the packet size exceeds the Maximum Transmission Unit (MTU) of the next hop, the router will drop the packet and send an ICMP 'Destination Unreachable' message. This flag is typically used in Path MTU Discovery (PMTUD) mechanisms. It has no dependencies on other flags but requires the network stack to handle ICMP error responses correctly.

Uso:
Enable this flag when you need to prevent packet fragmentation to improve network efficiency or to perform Path MTU Discovery. Use it with caution: if the path between your STM32 device and the destination contains a link with a smaller MTU than your packet size, the communication will fail. Ensure your application layer is prepared to handle dropped packets or reduced payload sizes if this flag is active.

`IP_FLAG_MF`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the 'More Fragments' bit in an IPv4 header.

Valore: `0x2000U`

Note:
When this bit is set (1), it indicates that the current IP packet is not the last fragment of a larger datagram. When cleared (0), it signifies the last fragment. This flag is used by the network stack's reassembly logic. It is a standard protocol constant defined by RFC 791 and should not be modified manually.

Uso:
Do not change this value as it is defined by the IPv4 protocol specification. It is used internally by the caOS network stack when parsing incoming fragmented packets or constructing outgoing ones. Modifying this will break network compatibility and cause packet reassembly failures.

`IP_FRAG_OFF_MASK`

File: `caos/net/inc/net_proto.h`

A bitmask used to extract the 13-bit fragment offset field from an IPv4 header.

Valore: `0x1FFFU`

Note:
The value 0x1FFF represents the 13 bits allocated for the fragment offset in the IP header. This constant is used during packet reassembly to identify the position of a data fragment within the original datagram. It is a fixed protocol constant defined by RFC 791 and should not be modified unless implementing a non-standard IP stack.

Uso:

Use this constant when parsing incoming IP packets to isolate the offset value from the flags field. Do not change this value; modifying it will cause the network stack to incorrectly calculate fragment positions, leading to corrupted data reassembly and dropped packets.

`IP_PROTO_ICMP`

File: `caos/net/inc/net_proto.h`

Enables or disables the Internet Control Message Protocol (ICMP) stack within the caOS networking layer.

Valore: `1U`

Note:
When set to 1U, the system includes code to process ICMP packets, such as Echo Requests (ping). Disabling it (0U) reduces the firmware binary size and memory footprint by removing ICMP handling logic. This flag is a prerequisite for network diagnostic tools and requires the base IP stack to be enabled.

Uso:
Set this to 1U if your device needs to respond to 'ping' requests for network connectivity testing. Disable it (0U) in production environments where you want to minimize the attack surface or save flash memory on resource-constrained STM32 devices.

`IP_PROTO_TCP`

File: `caos/net/inc/net_proto.h`

Defines the protocol number for TCP as specified in the IPv4 header.

Valore: `6U`

Note:
This constant is set to 6, which is the IANA-assigned protocol number for TCP. It is used by the network stack to identify incoming packets as TCP segments. Changing this value will cause the stack to fail to recognize TCP traffic, effectively disabling all TCP-based communication.

Uso:
This value should generally not be changed as it is defined by the Internet Protocol standard. It is used when constructing raw IP packets or filtering incoming traffic. Ensure this matches the standard value of 6 to maintain compatibility with external network devices and standard protocol stacks.

`IP_PROTO_UDP`

File: `caos/net/inc/net_proto.h`

Defines the protocol identifier for the User Datagram Protocol (UDP) within the caOS network stack.

Valore: `17U`

Note:
This constant is set to 17U, which is the standard IANA-assigned protocol number for UDP. It is used by the network layer to identify incoming packets and to populate the protocol field in

outgoing IP headers. It has no dependencies on other flags but must match the value expected by the underlying hardware abstraction layer (HAL) for packet filtering.

Uso:
You should never change this value as it is defined by the IPv4 protocol standard. It is used primarily when creating new socket structures or debugging packet headers in the network stack. If you are implementing a custom protocol, do not modify this constant; instead, define a new constant for your specific protocol ID.

`IP_TX_MTU_DEFAULT`

File: `caos/net/inc/net_proto.h`

Defines the default Maximum Transmission Unit (MTU) in bytes for outgoing IP packets.

Valore: `1500U`

Note:
This value sets the upper limit for the payload size of an IP packet before fragmentation occurs. It must be less than or equal to the physical interface's maximum frame size (e.g., 1500 for standard Ethernet). Reducing this value can decrease memory usage per buffer but may increase CPU overhead due to packet fragmentation.

Uso:
Adjust this value if your network hardware or specific protocol requirements (such as VPN tunnels or specific link-layer constraints) mandate a smaller MTU. Ensure that the system's memory pool for network buffers is large enough to accommodate this size plus protocol headers; setting this too high without sufficient RAM will lead to buffer overflows or allocation failures.

`ITM_BAUDRATE`

File: `caos/inc/itm.h`

Defines the transmission speed in bits per second for the Instrumentation Trace Macrocell (ITM) debug output.

Valore: `2000000UL`

Note:
This value sets the clock frequency for the SWO (Serial Wire Output) pin. It must match the baud rate configured in your debugger software (e.g., STM32CubeIDE or ST-Link Utility). If the value is too high for your hardware probe or trace clock settings, you will see garbled text or no output in the console. Typical values range from 115200 to 2000000.

Uso:
Adjust this value if you are experiencing data corruption in your debug logs or if your specific hardware probe requires a lower speed for stability. Ensure that the system core clock (HCLK) is high enough to support the requested baud rate, as the ITM clock is derived from the CPU frequency.

`KSTORE_DATE_DAY`

File: `caos/crypto/inc/keys_store.h`

Extracts the day component from a packed date value used in the key storage system.

Valore: `((v) & 0xFFU)`

Note:
This macro performs a bitwise AND operation with 0xFF to isolate the lower 8 bits of a provided date variable. It assumes the date is stored in a packed format where the day occupies the least significant byte. It has no dependencies on other RTOS flags but relies on the input 'v' being a valid packed date integer.

Uso:
Use this macro when retrieving or parsing key metadata from the secure storage. Change this only if the underlying packed date structure changes its bit-field layout. Incorrect usage will result in corrupted date values being returned, potentially causing key expiration logic to fail.

`KSTORE_DATE_MONTH`

File: `caos/crypto/inc/keys_store.h`

Extracts the month component from a packed 16-bit date value stored in the key management system.

Valore: `(((v) » 8) & 0xFFU)`

Note:
This macro performs a bitwise right shift by 8 bits followed by a mask of 0xFF to isolate the month field. It assumes the input 'v' is a 16-bit integer where the month is stored in the second byte. It has no dependencies on other flags but requires the input data to follow the specific caOS packed date format (typically bits 8-15).

Uso:
Use this macro when retrieving or validating the expiration date of cryptographic keys stored in the system. Do not modify this macro unless the underlying packed date structure in the key store is redefined. Providing an incorrectly formatted input will result in an invalid month value, potentially causing key validation logic to fail.

`KSTORE_DATE_PACK`

File: `caos/crypto/inc/keys_store.h`

A macro used to pack a calendar date (year, month, day) into a single 32-bit unsigned integer for efficient storage.

Valore: `(((u32)(y) « 16) | ((u32)(m) « 8) | (u32)(d))`

Note:
The macro performs bit-shifting to place the year in the upper 16 bits, the month in the middle 8 bits, and the day in the lower 8 bits. It requires three arguments (y, m, d). It is typically used in the key management system to timestamp cryptographic keys. Ensure the year value does not exceed 65535 to avoid overflow into other bit fields.

Uso:
Use this macro when you need to store or compare key expiration dates within the caOS key store. It is essential for maintaining a compact memory footprint in the key database. Do not use this for general-purpose date arithmetic, as it is strictly a formatting tool for storage.

KSTORE_DATE_YEAR

File: caos/crypto/inc/keys_store.h

Extracts the year component from a packed 32-bit date representation used in the key storage system.

Valore: (((v) » 16) & 0xFFU)

Note:
This macro performs a bitwise right shift by 16 bits followed by a mask of 0xFF to isolate the year byte. It assumes the input 'v' is a 32-bit integer where the year is stored in bits 16-23. It is a dependency for any function that validates key expiration dates or performs time-based key rotation logic.

Uso:
Use this macro when you need to read or verify the year of a key stored in the secure vault. Do not modify the shift or mask values unless the underlying data structure of the key metadata is updated, as incorrect values will result in corrupted date parsing and potential security validation failures.

KSTORE_SVC_IV_SIZE

File: caos/crypto/inc/keystore_service.h

Defines the fixed byte size of the Initialization Vector (IV) used for cryptographic operations within the Keystore Service.

Valore: 16

Note:
This constant sets the buffer size for IVs in AES-based encryption/decryption routines. Changing this value requires a full recompile of the crypto module and all dependent services. It must match the requirements of the underlying hardware acceleration (e.g., STM32 AES peripheral) or software library implementation. Typical value is 16 bytes for AES-128/256 in CBC or GCM modes.

Uso:
Modify this only if the security protocol or the underlying cryptographic algorithm requires a different IV length. Setting an incorrect value will cause cryptographic operations to fail with invalid parameter errors or result in corrupted data during decryption. Ensure that the hardware crypto engine supports the new length before changing this constant.

KSTORE_SVC_KEY_SIZE

File: caos/crypto/inc/keystore_service.h

Defines the fixed byte length for cryptographic keys managed by the caOS Keystore Service.

Valore: 32

Note:
This constant sets the buffer size for key storage operations. Enabling this ensures memory alignment for AES-256 keys. It must be consistent across all modules accessing the keystore; changing this value requires a full system recompile and may invalidate existing stored keys in non-volatile memory.

Uso:
Change this value only if your security requirements dictate a different key length (e.g., 16 for AES-128). Ensure the hardware crypto peripheral supports the new size. Setting this too low will cause truncation errors, while setting it too high will waste precious SRAM and Flash resources.

`KSTORE_SVC_LABEL_SIZE`

File: `caos/crypto/inc/keystore_service.h`

Defines the maximum character length allowed for labels assigned to cryptographic keys in the caOS keystore.

Valore: `6`

Note:
This constant sets the fixed-size buffer allocation for key identifiers. Increasing this value will increase the memory footprint of every keystore entry. It must be consistent across all modules that interface with the keystore service to prevent buffer overflows or truncation errors. The default value is 6 bytes.

Uso:
Increase this value if your application requires more descriptive or longer unique names for cryptographic keys. Decrease it only if you are extremely constrained by RAM and your naming convention allows for shorter identifiers. Ensure that any external storage or communication protocols expecting this specific size are updated accordingly to avoid data corruption.

`KSTORE_SVC_NONCE_SIZE`

File: `caos/crypto/inc/keystore_service.h`

Defines the fixed byte length of the cryptographic nonce used by the Keystore Service.

Valore: `12`

Note:
This constant sets the size of the initialization vector (IV) or nonce for encryption operations. Changing this value affects the memory allocation of internal buffers and the compatibility with external cryptographic standards. It must match the requirements of the underlying cipher suite (e.g., AES-GCM). Typical values are 12 bytes for GCM mode, though it may vary based on the specific security protocol implemented.

Uso:
Modify this value only if the security protocol or the hardware-accelerated cryptographic engine requires a different nonce length. Setting an incorrect value will cause cryptographic operations to fail or result in invalid ciphertext. Ensure that any change is synchronized with the peer devices or backend systems that expect a specific nonce size.

`KSTORE_SVC_P1_SIZE`

File: `caos/crypto/inc/keystore_service.h`

Defines the size in bytes of the primary partition buffer used by the keystore service.

Valore: `16`

Note:
This constant determines the memory allocation for the primary keystore storage slot. Increasing this value allows for larger cryptographic keys or more metadata but directly increases the static RAM footprint of the keystore service. It must be a multiple of the underlying flash page size if the service performs direct hardware writes. Typical values range from 16 to 256 depending on the security module requirements.

Uso:
Adjust this value when you need to store larger keys (e.g., moving from AES-128 to RSA-2048) or when the keystore service reports buffer overflow errors. Warning: setting this value too low will cause key storage operations to fail, while setting it too high may lead to stack or heap exhaustion in memory-constrained STM32 devices.

`KSTORE_SVC_P2_SIZE`

File: `caos/crypto/inc/keystore_service.h`

Defines the size of the secondary buffer (P2) used by the keystore service for cryptographic operations.

Valore: `16`

Note:
This constant sets the memory allocation in bytes for the secondary keystore processing stage. Increasing this value allows for larger cryptographic payloads or more complex key derivation functions but directly consumes more RAM from the system heap. It must be large enough to accommodate the maximum expected output size of the configured hash or encryption algorithms. Typical values range from 16 to 128 depending on the security requirements.

Uso:
Adjust this value if you encounter buffer overflow errors or 'insufficient memory' faults during cryptographic operations. Increase it if you switch to stronger encryption standards that require larger intermediate buffers. Do not set this value unnecessarily high to avoid wasting precious RAM on resource-constrained STM32 devices.

`KSTORE_SVC_TAG_SIZE`

File: `caos/crypto/inc/keystore_service.h`

Defines the fixed byte size for the authentication tag used in the keystore service cryptographic operations.

Valore: `16`

Note:
This constant sets the length of the Message Authentication Code (MAC) or tag appended to encrypted data. Changing this value directly affects the memory layout of the keystore storage structures. It must match the tag size expected by the underlying hardware cryptographic peripheral or software library. Typical values are 16 bytes for AES-GCM or similar standards; values other than 16 may cause decryption failures or buffer overflows if the storage buffers are not sized accordingly.

Uso:
Change this value only if the security protocol or the cryptographic algorithm used by the keystore service is updated to require a different tag length. Ensure that all existing stored keys

are re-encrypted or cleared before changing this value, as a mismatch will render stored data unreadable. Incorrect values will lead to integrity check failures during key retrieval.

`LPUART_STD_BAUD`

File: `os_config.h`

Defines the default baud rate for the Low Power UART (LPUART) peripheral in the caOS RTOS.

Valore: `115200U`

Note:
This constant sets the communication speed in bits per second. It directly affects the clock prescaler calculation for the LPUART hardware. Ensure this value matches the baud rate configured on your terminal emulator (e.g., PuTTY or Tera Term). It is typically set to 115200U, but valid ranges depend on the specific STM32 LPUART clock source frequency.

Uso:
Change this value if your hardware interface requires a different communication speed (e.g., 9600 or 921600). If you set this incorrectly, you will see garbage characters or no output at all on your serial console. Always verify that the system clock configuration supports the requested baud rate to avoid framing errors.

`LPUART_STD_WAKE`

File: `os_config.h`

Enables the Low-Power UART (LPUART) wake-up capability for the system.

Valore: `1`

Note:
When set to 1, the LPUART peripheral is configured to trigger an interrupt that wakes the MCU from Stop or Standby power modes upon receiving data. This requires the LPUART clock source to be set to HSI or LSE to remain active during low-power states. If set to 0, the LPUART will not wake the system, potentially causing data loss if the MCU is in a deep sleep state.

Uso:
Enable this flag when your application needs to remain in a low-power state while waiting for incoming serial commands. Change this to 0 if you are not using LPUART or if you want to prevent serial traffic from waking the device to save power. Ensure your hardware design supports LPUART wake-up pins before enabling.

`MAX`

File: `caos/inc/common.h`

A macro that returns the greater of two provided values.

Valore: `(((a) > (b)) ? (a) : (b))`

Note:
This is a standard ternary-based comparison macro. It evaluates both arguments, so avoid passing expressions with side effects (e.g., 'MAX(x++, y)') as they will be executed twice. It

is type-agnostic but relies on the compiler to handle implicit type promotion between the two arguments.

Uso:
Use this for calculating buffer sizes, timeout durations, or threshold comparisons. Always ensure the arguments are of compatible types to prevent unexpected compiler warnings or truncation errors. Avoid using this with function calls that modify global state.

`MAX_SECURE_KEYS`

File: `caos/crypto/inc/keys_store.h`

Defines the maximum number of cryptographic keys that can be stored in the caOS secure key vault.

Valore: `20`

Note:
This constant determines the size of the static array allocated in RAM for key management. Increasing this value consumes more memory (sizeof(key_t) * MAX_SECURE_KEYS). It must be greater than or equal to the total number of unique keys required by your application tasks. If set too low, key registration functions will return an error code (ERR_KEY_STORAGE_FULL).

Uso:
Increase this value if your application needs to handle more concurrent encrypted connections or secure storage slots than the default 20. Ensure that your STM32 device has sufficient RAM before increasing this limit, as it directly impacts the heap/static memory footprint.

`MAX_TASK`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the maximum number of concurrent tasks allowed in the caOS scheduler.

Valori per MCU:

MCU	Valore
F103	5
F407	23
F429	23
F446	23
F746	90
H563	90
H747	93
H753	93

Note:
This constant determines the size of the internal Task Control Block (TCB) array. Increasing this value consumes more static RAM, as each task requires a dedicated memory slot regardless

of whether it is currently active. It must be set to a value greater than or equal to the total number of tasks created in your application. If you attempt to create more tasks than this limit, the system will trigger an assertion or return an error code during initialization.

Uso:
Adjust this value when adding or removing tasks from your project. Set it to the exact number of tasks you intend to run plus a small buffer for future expansion. Do not set this value excessively high, as it will waste precious RAM on your STM32 microcontroller. Always verify that your total RAM usage remains within the limits of your specific MCU model after increasing this constant.

`MAX_TIMER`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the maximum number of software timers that can be active simultaneously in the caOS system.

Valori per MCU:

MCU	Valore
F103	5
F407	14
F429	14
F446	14
F746	32
H563	32
H747	32
H753	32

Note:
This constant allocates a static array in memory to track timer control blocks. Increasing this value consumes more RAM (sizeof(Timer_t) * MAX_TIMER). It is hardware-dependent; higher-performance MCUs like the H7 series support more timers due to larger memory availability. Ensure this value is greater than or equal to the total number of unique software timers initialized in your application code.

Uso:
Increase this value if your application requires more concurrent software timers and you encounter 'Timer Allocation Failed' errors during runtime. Decrease it if you need to optimize RAM usage on memory-constrained devices like the F103. Do not set this value arbitrarily high, as it wastes static memory.

`MAX_TOTAL_KEY_STORAGE`

File: `caos/crypto/inc/keys_store.h`

Defines the maximum total memory in bytes allocated for storing cryptographic keys within the system.

Valore: 2048

Note:
This constant determines the static buffer size for the key management module. Increasing this value consumes more RAM from the heap or static data segment. It must be large enough to accommodate the sum of all individual key sizes plus internal metadata overhead. If set too low, key registration functions will return an 'out of memory' error.

Uso:
Adjust this value when your application needs to store more keys or larger key types (e.g., switching from AES-128 to RSA-2048). Ensure the total size does not exceed the available RAM on your STM32 target. Always verify that the system heap remains sufficient for other RTOS tasks after increasing this constant.

MCU_HAS_ETH

File: hw/f1xx/f103/objmap.h
File: hw/f4xx/f407/objmap.h
File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h
File: hw/h5xx/h563/objmap.h
File: hw/h7xx/h747/objmap.h
File: hw/h7xx/h753/objmap.h

A boolean flag indicating whether the target microcontroller hardware includes an integrated Ethernet MAC peripheral.

Valori per MCU:

MCU	Valore
F103	0U
F407	1U
F429	1U
F446	0U
F746	1U
H563	1U
H747	1U
H753	1U

Note:
When set to 1U, the caOS network stack and hardware abstraction layer (HAL) will initialize Ethernet-related registers and interrupt vectors. When set to 0U, these features are disabled to save memory and prevent illegal memory access. This flag must match the specific STM32 part number; enabling it on a chip without an Ethernet controller will cause a hard fault during system initialization.

Uso:
Change this value only when porting the project to a different STM32 MCU variant. If your application requires network connectivity, ensure this is set to 1U for supported chips (e.g., F407, H7 series). If you are using a chip without Ethernet (e.g., F103, F446), this must remain 0U, or the build will fail during the linking stage due to missing peripheral definitions.

`MCU_HAS_GPDMA`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

A boolean flag indicating if the target microcontroller includes a General Purpose Direct Memory Access (GPDMA) controller.

Valori per MCU:

MCU	Valore
F103	0U
F407	0U
F429	0U
F446	0U
F746	0U
H563	1U
H747	0U
H753	0U

Note:
When set to 1U, the caOS kernel enables support for the GPDMA peripheral, which is distinct from the older DMA controllers found in F4/F7 series. Enabling this requires the hardware to support the GPDMA architecture (e.g., STM32H5 series). If set to 0U, the system will use standard DMA or polling methods. This flag is hardware-dependent and must match the specific MCU datasheet.

Uso:
Change this value only when porting caOS to a new STM32 series. Set to 1U if your MCU features the newer GPDMA block to allow the OS to offload data transfers efficiently. Setting this to 1U on an MCU that lacks GPDMA will result in compilation errors or hard faults during peripheral initialization.

`MCU_HAS_QSPI`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/f7xx/f767/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

A boolean flag indicating if the target STM32 microcontroller features a hardware Quad-SPI (QSPI) peripheral.

Valori per MCU:

MCU	Valore
F103	0U
F407	0U
F429	0U
F446	1U
F746	1U
F767	1U
H563	1U
H747	1U
H753	1U

Note:
When set to 1U, the caOS kernel enables drivers and memory-mapped access routines for external QSPI flash memory. When set to 0U, these features are disabled to save code space and prevent compilation errors on MCUs lacking the peripheral. This flag must match the specific hardware capabilities of the selected MCU; enabling it on an unsupported chip will cause linker errors or hard faults.

Uso:
Set this to 1U only if your specific STM32 model includes a QSPI controller and you intend to interface with external flash memory. If you are using an F103 or F407 series chip, this must remain 0U. Always verify your MCU datasheet's peripheral list before changing this value to avoid undefined behavior.

`MCU_HAS_RNG`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

A boolean flag indicating whether the target STM32 microcontroller has a built-in hardware Random Number Generator (RNG) peripheral.

Valori per MCU:

MCU	Valore
F103	0U
F407	1U
F429	1U
F446	0U
F746	1U
H563	1U
H747	1U
H753	1U

Note:
When set to 1U, the caOS kernel will utilize the hardware RNG for entropy-based features such as secure task stack canaries or cryptographic seeding. If set to 0U, the system will fall back to a software-based pseudo-random number generator or disable RNG-dependent features. This flag must match the specific hardware capabilities of the MCU defined in the datasheet; enabling it

on an MCU without an RNG peripheral will cause a hard fault or undefined behavior during peripheral initialization.

Uso:
Set this value based on the specific STM32 series being used. You should change this only when porting the project to a different MCU model. If you are unsure, check the 'Reference Manual' for your specific STM32 part under the 'RNG' section. Incorrect configuration will lead to initialization errors or failure of security-related features.

`MCU_HAS_USB`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

A hardware abstraction flag that indicates whether the target STM32 microcontroller includes a built-in USB peripheral.

Valori per MCU:

MCU	Valore
F103	0U
F407	1U
F429	1U
F446	1U
F746	1U
H563	1U
H747	1U
H753	1U

Note:
When set to 1U, the caOS kernel enables USB-related drivers and memory allocation for USB stacks. When set to 0U, all USB-related code is excluded from the build to save flash memory. This flag is strictly dependent on the specific MCU part number; enabling it on an MCU without USB hardware will cause compilation errors or hard faults during peripheral initialization.

Uso:
Change this value only when porting caOS to a new STM32 chip. You must set this to 1U if your application requires USB communication (e.g., CDC, HID, or MSC). If you are working on a chip like the F103, ensure this is set to 0U to prevent the compiler from attempting to access non-existent USB registers.

`MCU_NO_ETH`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f446/objmap.h`

A configuration flag that disables the Ethernet peripheral driver and stack within the caOS RTOS.

Valori per MCU:

MCU	Valore
F103	1
F446	1

Note:
When set to 1, the Ethernet hardware abstraction layer and associated network buffers are excluded from the build. This reduces the memory footprint (RAM and Flash) and prevents the RTOS from attempting to initialize non-existent or unused network hardware. It is independent of other peripherals but must be set to 1 for STM32 models like F103 and F446 that lack integrated Ethernet MAC controllers.

Uso:
Set this to 1 for any STM32 target that does not have a built-in Ethernet peripheral to avoid compilation errors or runtime faults. You should only set this to 0 if you are using a specific MCU variant that supports Ethernet and you intend to use the networking stack. Setting this to 0 on an unsupported MCU will lead to undefined behavior or hard faults during system initialization.

`MDNS_CACHE_FLUSH`

File: `caos/net/inc/net_proto.h`

Defines the bitmask flag used to trigger an immediate flush of the mDNS resource record cache.

Valore: `0x8000U`

Note:
When this flag is set in the mDNS control register, the system clears all cached mDNS entries to force a re-discovery of network services. It is a bitwise constant (0x8000U) and should be used in conjunction with the mDNS command interface. It has no dependencies on other flags but requires the mDNS stack to be initialized.

Uso:
Use this flag when you need to resolve stale network service information or after a significant network topology change. Do not set this flag continuously in a loop, as it will cause excessive network traffic and CPU overhead due to constant re-querying of the local network.

`MDNS_DST_IP`

File: `caos/net/inc/net_proto.h`

Defines the IPv4 multicast destination address used for mDNS (Multicast DNS) service discovery packets.

Valore: `{224U,0U,0U,251U}`

Note:
The value represents the standard mDNS multicast address 224.0.0.251 in an array format. Modifying this will cause the device to stop responding to or sending mDNS queries on the standard network, effectively isolating it from local service discovery. It must remain as {224U, 0U, 0U, 251U} for standard network compatibility.

Uso:

Change this only if you are operating on a non-standard, isolated network that requires a custom multicast group for service discovery. Incorrect values will result in the device being invisible to other network nodes using standard mDNS protocols.

`MDNS_DST_MAC`

File: `caos/net/inc/net_proto.h`

Defines the standard IPv4 multicast MAC address used for mDNS discovery packets.

Valore: `{0x01U,0x00U,0x5EU,0x00U,0x00U,0xFBU}`

Note:
This constant represents the IEEE 802.3 multicast address 01:00:5E:00:00:FB. It is required by the network stack to filter incoming mDNS traffic at the hardware level. Changing this value will cause the device to stop receiving mDNS queries and announcements, effectively making the device invisible to network discovery services.

Uso:
Do not modify this value unless you are implementing a custom or non-standard multicast protocol. It is used by the caOS network driver to configure the Ethernet MAC address filter. Ensure that the hardware peripheral is initialized to accept this multicast group, otherwise, the stack will not process mDNS packets.

`MDNS_PORT`

File: `caos/net/inc/net_proto.h`

Defines the UDP port number used for mDNS (Multicast DNS) service discovery.

Valore: `5353U`

Note:
This constant sets the destination port for mDNS packets. It must be set to 5353 to comply with the RFC 6762 standard. Changing this value will prevent the device from being discovered by standard mDNS clients like Bonjour or Avahi. It is a dependency for the caOS network stack's zero-configuration networking module.

Uso:
Keep this value at 5353U for standard network interoperability. Only change this value if you are operating in a private, isolated network environment that requires a non-standard port for custom service discovery protocols. Incorrect values will result in the device becoming invisible to network discovery tools.

`MDNS_TTL`

File: `caos/net/inc/net_proto.h`

Defines the Time-To-Live (TTL) value in seconds for mDNS resource records.

Valore: `120U`

Note:
This constant determines how long network peers should cache the mDNS service information before re-querying. The value is an unsigned integer, typically set to 120 seconds. Lowering this

value increases network traffic due to more frequent queries, while increasing it reduces traffic but may cause stale service information if the device IP or status changes.

Uso:
Adjust this value if your device frequently changes its network configuration or if you notice other devices on the network failing to discover your service after a reconnection. A value of 120 is a standard balance for most local networks; avoid setting this to extremely low values (e.g., < 10) to prevent network congestion.

`MIN`

File: `caos/inc/common.h`

A macro that returns the smaller of two provided values.

Valore: `(((a) < (b)) ? (a) : (b))`

Note:
This is a functional macro that performs a comparison between two inputs. It is side-effect prone if the arguments contain increment or decrement operators (e.g., MIN(a++, b)), as the chosen argument will be evaluated twice. It has no dependencies on other RTOS flags and works with any comparable data type.

Uso:
Use this macro to safely determine the minimum of two variables without writing manual if-else blocks. Warning: Avoid passing expressions with side effects as arguments to prevent unexpected behavior, such as double-incrementing a counter.

`MIN_KEY_SIZE`

File: `caos/crypto/inc/keys_store.h`

Defines the minimum allowed length in bytes for cryptographic keys stored in the system.

Valore: `16`

Note:
This constant enforces a security floor for key generation and storage. Setting this value higher increases security but may cause key generation functions to fail if the requested entropy or algorithm requires smaller keys. It is typically set to 16 (128 bits) to comply with AES standards. Ensure that all hardware-accelerated crypto peripherals support the chosen minimum size.

Uso:
Increase this value if your security policy requires stronger encryption (e.g., 32 for 256-bit keys). Decrease it only if you are using legacy algorithms that explicitly require shorter keys. Warning: setting this too low may expose the system to brute-force attacks, while setting it too high may cause runtime errors in modules that expect smaller key buffers.

`MODBUS_RX_BUF_SIZE`

File: `os_config.h`

Defines the maximum size in bytes for the Modbus reception buffer.

Valore: `270U`

Note:
This constant determines the memory allocation for incoming Modbus frames. The value must be large enough to accommodate the maximum expected PDU size plus any protocol overhead. It is typically set to 270 to support the Modbus standard maximum frame size of 256 bytes plus additional framing bytes. Increasing this value consumes more RAM, while setting it too low will cause frame truncation and CRC errors.

Uso:
Adjust this value if your application needs to handle larger custom Modbus frames or if you need to optimize RAM usage on memory-constrained devices. Ensure the value is at least 256. If you encounter 'Buffer Overflow' or 'Invalid Frame' errors during communication, verify that this size is sufficient for the specific Modbus function codes being used.

`MODBUS_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum duration in milliseconds to wait for a response from a Modbus slave device.

Valore: `1000U`

Note:
This constant sets the timeout threshold for the Modbus master state machine. If no valid response is received within this period, the transaction is marked as failed. It depends on the underlying UART baud rate and the physical latency of the bus. Typical values range from 100ms to 2000ms depending on the network topology.

Uso:
Increase this value if you experience frequent 'timeout' errors on long or noisy communication lines. Decrease it if you need faster error recovery in high-speed, reliable networks. Setting this value too low will cause valid responses to be discarded, while setting it too high will make the system unresponsive during communication failures.

`MPU_ACCESS_NONE`

File: `caos/inc/mpu.h`

A configuration constant representing a memory region with no read, write, or execute permissions.

Valore: `0`

Note:
When applied to an MPU region, this setting triggers a MemManage fault if the CPU attempts to access the memory address. It is the default state for uninitialized or restricted memory segments. It has no dependencies on other flags but acts as the base security level for the MPU configuration.

Uso:
Use this value when defining MPU regions that should be completely inaccessible to tasks to prevent buffer overflows or unauthorized memory access. Do not use this for memory regions where your application code or data resides, as it will cause the system to crash immediately upon access.

`MPU_ACCESS_RDONLY`

File: `caos/inc/mpu.h`

Defines the memory protection unit (MPU) attribute for read-only memory regions.

Valore: `1`

Note:
When enabled, this flag configures the hardware MPU to trigger a memory management fault if a write operation is attempted on the associated memory region. It is typically used in conjunction with memory region definition structures. It depends on the hardware support for MPU on the specific STM32 series being used.

Uso:
Use this flag when defining memory regions for constants, flash-based code, or read-only lookup tables to prevent accidental data corruption. Ensure that the memory region is not intended to be modified at runtime; setting this on a RAM region that requires updates will cause the system to crash with a MemManage fault.

`MPU_ACCESS_RDWR`

File: `caos/inc/mpu.h`

Defines the Memory Protection Unit (MPU) access permission level for Read and Write operations.

Valore: `2`

Note:
When set to 2, this constant configures the MPU region to allow both read and write access to the associated memory block. It is typically used in conjunction with other MPU configuration flags to define memory attributes. Disabling or changing this value incorrectly will trigger a MemManage fault if the CPU attempts to write to a region restricted to read-only or no-access.

Uso:
Change this value when you need to grant or restrict write permissions to specific memory regions, such as shared buffers or peripheral registers. Use this when you encounter hard faults during memory access operations. Ensure that the memory region is properly aligned and sized according to the STM32 MPU hardware requirements before applying this flag.

`MPU_CANARY_REGION_MSP`

File: `caos/inc/mpu.h`

Enables or disables the MPU memory protection region specifically for the Main Stack Pointer (MSP) stack overflow detection.

Valore: `0`

Note:
When set to 1, the MPU configures a hardware-enforced guard zone at the end of the MSP stack; any write access to this region triggers a MemManage fault. When set to 0, this hardware protection is disabled. This flag depends on MPU_ENABLED being set to 1. Valid values are 0 (disabled) or 1 (enabled).

Uso:

Enable this (set to 1) during development and debugging to catch stack overflows immediately via hardware exceptions. Disable it (set to 0) only if you need to reclaim the MPU region for other memory mapping purposes or if you are running on hardware that does not support sufficient MPU regions. Warning: disabling this removes a critical safety mechanism that prevents silent memory corruption.

`MPU_CANARY_REGION_PSP_END`

File: `caos/inc/mpu.h`

Defines the MPU region index used to protect the end of the Process Stack Pointer (PSP) memory area.

Valore: `2`

Note:
This constant sets the specific hardware MPU slot (0-7) reserved for stack overflow detection. Enabling this requires the MPU to be active and the stack memory to be aligned to the MPU region size requirements. If set to an index already used by another memory region, it will cause a configuration conflict or system fault.

Uso:
Change this value only if the hardware memory map or the MPU region allocation scheme is modified. It is used to solve stack overflow issues by triggering a MemManage fault when the stack pointer exceeds the defined boundary. Ensure the chosen index does not overlap with Flash, RAM, or peripheral regions defined elsewhere in the system.

`MPU_CANARY_REGION_PSP_START`

File: `caos/inc/mpu.h`

Enables the MPU memory protection region for the Process Stack Pointer (PSP) start address to detect stack overflows.

Valore: `1`

Note:
When enabled, the MPU configures a hardware-enforced boundary at the beginning of the task stack. If the stack pointer moves below this address, a MemManage fault is triggered. This flag depends on MPU_ENABLED being set to 1. Typical value is 1 for production builds and 0 only for specific low-memory debugging scenarios.

Uso:
Enable this to prevent silent memory corruption caused by stack overflows. Change this to 0 only if you are performing advanced memory mapping that conflicts with the default stack placement, though this is strongly discouraged as it removes a critical safety mechanism.

`MPU_REGION_COUNT`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`

File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the total number of hardware memory protection regions available on the specific STM32 microcontroller.

Valori per MCU:

MCU	Valore
F103	8U
F407	8U
F429	8U
F446	8U
F746	8U
H563	16U
H747	16U
H753	16U

Note:
This constant sets the limit for the Memory Protection Unit (MPU) configuration. Enabling this allows the RTOS to isolate tasks and protect memory areas. The value is hardware-dependent: F1/F4/F7 series typically support 8 regions, while H5/H7 series support 16. Setting this value higher than the hardware capability will cause MPU configuration errors or hard faults.

Uso:
You should change this value only when porting the RTOS to a different STM32 family. It is used by the kernel to allocate memory protection tables. Ensure the value matches the datasheet specification for your specific MCU part number; an incorrect value will lead to unpredictable system behavior or immediate crashes during kernel initialization.

`MQTT_KEEPALIVE_SEC`

File: `os_config.h`

Defines the interval in seconds at which the MQTT client sends a PINGREQ packet to the broker to maintain the connection.

Valore: `60U`

Note:
This value determines the timeout period for the broker to consider the client disconnected. If set too low, it increases network traffic and power consumption; if set too high, the system may take longer to detect a dropped connection. It must be less than the broker's maximum allowed keep-alive threshold. Typical values range from 30 to 300 seconds.

Uso:
Adjust this value if the broker frequently disconnects the device or if you need to optimize for low-power battery operation. Ensure the value is synchronized with the broker's configuration to prevent unexpected session termination.

`MQTT_RX_BUF_SIZE`

File: `os_config.h`

Defines the maximum size in bytes of the buffer used to store incoming MQTT messages.

Valore: `256U`

Note:
This value determines the memory footprint of the MQTT task. If set too low, incoming packets exceeding this size will be truncated or dropped. It must be large enough to accommodate the largest expected MQTT payload plus protocol headers. Typical values range from 256 to 2048 depending on available RAM and application requirements.

Uso:
Increase this value if you observe incomplete message reception or errors when receiving large MQTT payloads. Decrease it if your system is running low on heap memory and you are only handling small control messages. Ensure the value is a multiple of 4 for optimal memory alignment on STM32 architectures.

`NET_BUF_COUNT`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/f7xx/f767/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the total number of network packet buffers available in the system memory pool.

Valori per MCU:

MCU	Valore
F103	0
F407	8
F429	16
F446	8
F746	64
F767	64
H563	64
H747	64
H753	64

Note:
This constant determines the maximum number of concurrent network packets the stack can hold. Increasing this value consumes more RAM (each buffer is typically 1536 bytes). If set to 0, networking features are disabled. Values must be chosen based on available SRAM; for example, F7/H7 series support higher counts due to larger memory capacity, while F103 lacks sufficient resources for network buffering.

Uso:
Increase this value if the system experiences 'packet dropped' errors or fails to handle high-traffic bursts. Decrease it if the application encounters hard faults or memory allocation failures during startup. Ensure the value is sufficient for your application's throughput requirements, but do not exceed available heap space.

NET_BUF_DATA_SIZE

File: caos/net/inc/net_buf.h

Defines the actual payload capacity in bytes for a network buffer by subtracting the header overhead from the total buffer size.

Valore: (NET_BUF_SIZE - NET_BUF_HDR_SIZE)

Note:
This constant is derived from NET_BUF_SIZE and NET_BUF_HDR_SIZE. It represents the maximum amount of application data that can fit into a single network packet. If NET_BUF_SIZE is too small, this value may become negative or insufficient for standard MTU requirements, potentially causing memory corruption or packet fragmentation issues.

Uso:
Adjust this value only if you need to change the total buffer size (NET_BUF_SIZE) to accommodate larger network packets. Ensure that the resulting size is sufficient for your protocol's MTU (e.g., 1500 bytes for Ethernet). Always verify that the total memory allocated for buffers does not exceed the available RAM on the STM32.

NET_BUF_F_IN_USE

File: caos/net/inc/net_buf.h

A bitmask flag indicating that a specific network buffer is currently allocated and being used by the system.

Valore: (1U « 0)

Note:
When this bit is set in the buffer's status field, the memory manager considers the buffer busy and will not reallocate it. If cleared, the buffer is marked as free for reuse. This flag is typically checked by the network stack's allocation functions to prevent memory leaks or data corruption. It is a fundamental flag for the buffer management lifecycle.

Uso:
You should never manually toggle this flag in your application code; it is managed internally by the caOS network stack. If you notice that network buffers are not being freed, check if your code is correctly passing buffers back to the stack after processing. Modifying this flag directly will lead to memory leaks or system crashes due to double-allocation of the same memory block.

NET_BUF_F_RAW

File: caos/net/inc/net_buf.h

Flag to disable automatic checksum calculation for a network buffer.

Valore: (1U « 2) /* send as is: no checksum insertion by

Note:
When this flag is set in the buffer flags, the caOS network stack skips the automatic insertion of checksums (e.g., TCP/UDP/IP checksums) before transmission. This is typically used when the application layer or a hardware offload engine is responsible for calculating the checksum, or when sending raw packets that do not require standard protocol checksums. It is a bitmask value (1U « 2).

Uso:
Use this flag when you are manually constructing a packet and have already calculated the checksum, or when you are sending custom protocol frames that do not follow standard checksum requirements. Warning: If you enable this flag without providing a valid checksum, the receiving device will likely drop the packet as corrupted.

`NET_BUF_F_TX`

File: `caos/net/inc/net_buf.h`

A bitmask flag indicating that the network buffer is currently designated for transmission (TX) operations.

Valore: `(1U ≪ 1)`

Note:
This flag is used by the network stack to distinguish between incoming (RX) and outgoing (TX) buffers. When set, the buffer is managed by the transmission logic and should not be modified by the RX interrupt service routines. It is typically used in conjunction with buffer allocation functions and must be cleared once the transmission is complete to allow the buffer to be recycled.

Uso:
Use this flag when manually allocating or inspecting buffers within the network stack to ensure the buffer is correctly routed to the hardware DMA or MAC peripheral. Do not manually toggle this bit unless you are implementing custom network drivers, as incorrect state management will lead to memory leaks or buffer corruption in the network pool.

`NET_BUF_HDR_SIZE`

File: `caos/net/inc/net_buf.h`

Defines the fixed size in bytes reserved for the network buffer header metadata.

Valore: `64U`

Note:
This value determines the memory offset where the actual payload data begins within a network buffer. Increasing this value consumes more RAM per buffer but allows for larger protocol headers (e.g., adding custom tunneling or encryption headers). It must be large enough to accommodate the stack's internal headers; otherwise, packet corruption will occur. Typical values are powers of 2 to ensure memory alignment.

Uso:
Adjust this value if you are implementing custom network protocols that require additional metadata space before the payload. Do not decrease this value below the default unless you are certain the underlying network stack requires less header space, as doing so will cause buffer overflows and system instability.

`NET_BUF_HEADROOM`

File: `caos/net/inc/net_buf.h`

Defines the number of bytes reserved at the beginning of a network buffer for protocol headers.

Valore: `128U`

Note:
This value sets the offset where the actual payload data begins within a network packet buffer. Increasing this value allows for more layers of encapsulation (e.g., adding VLAN tags or tunneling headers) without reallocating the buffer. It must be large enough to accommodate the maximum expected stack of headers (Ethernet + IP + TCP/UDP + custom headers). Typical values are powers of 2, and it must be less than the total buffer size.

Uso:
Increase this value if you encounter buffer overflow errors or kernel panics when adding new protocol layers or tunneling protocols. Decrease it only if memory is extremely constrained and you are certain the header stack will never exceed the new limit. Setting this too low will cause memory corruption or packet drops when headers are prepended.

`NET_BUF_INVALID`

File: `caos/net/inc/net_buf.h`

A sentinel value representing an uninitialized or invalid network buffer handle.

Valore: `0xFFFFU`

Note:
This constant is used as a null-pointer equivalent for network buffer descriptors. When a function returns this value, it indicates that the requested buffer allocation failed or the buffer reference is no longer valid. It is defined as 0xFFFFU to ensure it falls outside the range of valid memory-mapped buffer indices.

Uso:
Use this constant to check the success of network buffer allocation functions. Always compare the returned handle against NET_BUF_INVALID before attempting to access buffer data to prevent memory corruption or system crashes. Do not modify this value unless the underlying buffer pool architecture is redefined.

`NET_BUF_SIZE`

File: `caos/net/inc/net_buf.h`

Defines the fixed size in bytes for each network packet buffer allocated by the caOS networking stack.

Valore: `2048U`

Note:
This value determines the maximum payload size a single network buffer can hold. Increasing this value consumes more RAM from the heap for every allocated buffer, which can lead to memory exhaustion if the pool size is not adjusted accordingly. It must be large enough to accommodate the Maximum Transmission Unit (MTU) of the underlying network interface, typically 1500 bytes for Ethernet plus protocol headers.

Uso:
Increase this value if you encounter packet fragmentation or if your application needs to handle jumbo frames. Decrease it only if you are extremely constrained by RAM and are certain that your network traffic will never exceed the smaller limit. Setting this value too low will cause incoming packets to be dropped or truncated, leading to communication failures.

`NET_HANDLER_MAX`

File: `caos/net/inc/net.h`

Defines the maximum number of concurrent network socket handlers allowed in the system.

Valore: `8U`

Note:
This constant determines the size of the internal static array used to track active network connections. Increasing this value consumes more RAM in the .bss section. It must be greater than or equal to the number of simultaneous TCP/UDP sockets your application intends to open. If set too low, new connection attempts will be rejected by the network stack.

Uso:
Adjust this value based on your application's memory constraints and communication requirements. Increase it if your application needs to handle more simultaneous connections (e.g., a web server with multiple clients). Decrease it to save RAM if your device only communicates with a single server. Ensure that the total memory usage does not exceed the STM32's available SRAM.

`NET_IFACE_INVALID`

File: `caos/net/inc/net_iface.h`

A sentinel value representing an uninitialized or non-existent network interface handle.

Valore: `0xFFU`

Note:
This constant is used as a null-equivalent for network interface pointers or IDs. When a function returns this value, it indicates that the requested interface could not be found or is not currently active. It is typically used in comparison checks against interface handles returned by the network stack.

Uso:
Use this constant to validate interface handles before performing operations like sending or receiving packets. Always check if your interface handle equals NET_IFACE_INVALID to prevent null pointer dereferences or accessing invalid memory regions. Do not use this value as a valid interface index in your application code.

`NET_IFACE_MAX`

File: `caos/net/inc/net_iface.h`

Defines the maximum number of network interfaces that can be registered simultaneously in the caOS network stack.

Valore: `2U`

Note:
This constant determines the size of the internal interface registry array. Increasing this value consumes more static RAM for the interface control blocks. It must be set to at least 1, and it is typically constrained by the available memory and the number of physical or virtual hardware peripherals (e.g., Ethernet, Wi-Fi, or PPP) present in the system.

Uso:

Increase this value if your application needs to support multiple network connections simultaneously, such as a dual-homed gateway or a system with both Ethernet and Wi-Fi. If you set this value higher than the number of actual hardware drivers initialized, you will waste RAM; if set too low, additional interfaces will fail to register during system startup.

NET_MAC_FILTER_MAX

File: caos/net/inc/net.h

Defines the maximum number of MAC addresses that can be stored in the network hardware filter list.

Valore: 2U

Note:
This constant determines the size of the internal array used by the network stack to manage MAC address filtering. Increasing this value consumes more static RAM. It is typically used in conjunction with ca_net_filter_mac_set to whitelist specific devices. The default value is 2U, which is sufficient for simple point-to-point or gateway configurations.

Uso:
Increase this value if your application needs to filter or whitelist more than two specific MAC addresses simultaneously. If you set this too high, you will waste memory; if you set it too low, calls to ca_net_filter_mac_set will fail once the limit is reached. Ensure you have enough RAM before increasing this constant.

NET_MPU_REGION

File: caos/net/inc/net_buf.h

Defines the specific MPU memory region index reserved for network buffer operations.

Valore: 3U

Note:
This constant sets the hardware MPU slot used to enforce memory protection on network packet buffers. It must be a valid MPU region index supported by the STM32 hardware (typically 0-7). Changing this value requires ensuring that the corresponding MPU configuration in the system startup code is updated to match, otherwise, the system will trigger a MemManage fault when accessing network buffers.

Uso:
Change this value only if the default MPU region conflicts with other system-critical memory protections or if the hardware abstraction layer requires a specific region for DMA-capable network memory. Ensure that the chosen region is not already assigned to the RTOS kernel stack or peripheral memory maps to avoid system instability.

NET_PROTO_ARP

File: caos/net/inc/net_buf.h

Enables or disables the Address Resolution Protocol (ARP) support in the caOS network stack.

Valore: 0x01U

Note:
When set to 0x01U, the system includes the logic to resolve IP addresses to MAC addresses. Disabling this (0x00U) will prevent the device from communicating with other nodes on a local Ethernet network unless static ARP entries are manually configured. This flag is a dependency for IPv4 networking modules.

Uso:
Enable this flag when your application needs to communicate over an Ethernet network using IPv4. Disable it only if you are implementing a custom, non-ARP based protocol or if you are operating in a point-to-point environment where ARP is explicitly not required to save memory and code space.

`NET_PROTO_IP4`

File: `caos/net/inc/net_buf.h`

Enables IPv4 protocol support within the caOS networking stack.

Valore: `0x02U`

Note:
When set to 0x02U, the system includes the IPv4 header processing logic and routing tables. Disabling this flag will remove IPv4 functionality, reducing the binary footprint but preventing communication over standard IPv4 networks. This flag is often a dependency for higher-level protocols like TCP or UDP if they are configured to run over IPv4.

Uso:
Enable this flag when your application needs to communicate over an IPv4 network. Change this value only if you are strictly using IPv6 or a custom non-IP protocol to save memory. Ensure that your network interface driver is compatible with IPv4 before enabling this, otherwise, the stack may attempt to process unsupported packets.

`NET_PROTO_IP6`

File: `caos/net/inc/net_buf.h`

Enables IPv6 protocol support within the caOS network stack.

Valore: `0x03U`

Note:
When set to 0x03U, the system allocates memory structures and enables logic for IPv6 packet processing. This flag is a dependency for any network services requiring IPv6 addressing. It must be consistent across all network modules to prevent memory alignment issues or stack overflows. Valid values are 0x00U (disabled) or 0x03U (enabled).

Uso:
Enable this flag when your application needs to communicate over IPv6 networks. Change this value if you are migrating from an IPv4-only environment to a dual-stack or IPv6-only setup. Warning: Enabling this increases the static memory footprint of the network buffer pool; ensure your heap size is sufficient before activation.

`NET_PROTO_NONE`

File: `caos/net/inc/net_buf.h`

A configuration flag indicating that no network protocol stack is currently initialized or active.

Valore: `0x00U`

Note:
When set to 0x00U, the network buffer management system bypasses all protocol-specific processing. This flag is typically used as a default state or a sentinel value in the network stack initialization sequence. It has no dependencies on other flags but must be checked before attempting to access protocol-specific headers or payload structures.

Uso:
Use this value during system initialization or when the network interface is explicitly disabled to prevent the stack from attempting to process incoming or outgoing packets. Changing this value incorrectly can lead to null pointer dereferences or memory corruption if the system expects a valid protocol handler to be present.

`NET_QUEUE_DEPTH`

File: `caos/net/inc/net_queue.h`

Defines the maximum number of network packets that can be buffered in the internal queue before dropping new incoming data.

Valore: `128U`

Note:
Increasing this value consumes more RAM from the heap, as each slot reserves space for a packet descriptor. It must be a power of two if the underlying implementation uses bitwise masking for circular buffer indexing. Typical values range from 16 to 256 depending on available memory and traffic burst intensity.

Uso:
Increase this value if the system experiences packet loss during high-traffic bursts or when the processing task is temporarily preempted by higher-priority threads. Decrease it if the system is running low on heap memory and network throughput requirements are low.

`NET_ROUTE_MAX`

File: `os_config.h`

Defines the maximum number of entries allowed in the network routing table.

Valore: `8U`

Note:
This constant determines the size of the static array used to store routing paths. Increasing this value consumes more RAM but allows the device to manage more complex network topologies or subnets. It must be a positive integer, typically ranging from 4 to 32 depending on available heap/stack memory.

Uso:

Increase this value if your device needs to communicate with multiple gateways or subnets and you encounter 'route not found' errors. Decrease it to save RAM if your device only communicates with a single local gateway.

`NTP_EPOCH_DELTA`

File: `caos/net/inc/net_proto.h`

The constant representing the number of seconds between the NTP epoch (January 1, 1900) and the Unix epoch (January 1, 1970).

Valore: `2208988800UL`

Note:
This value is used to convert NTP timestamps into standard Unix timestamps used by the system clock. It is a fixed constant of 2208988800 seconds. Changing this value will cause incorrect system time synchronization and will break all time-dependent network protocols like TLS/SSL certificate validation.

Uso:
This value should generally not be changed. It is used internally by the caOS network stack when parsing NTP packets. You only need to verify this value if you are porting the stack to a non-standard time reference or if you encounter significant time offsets during network synchronization.

`NTP_POLL_MS`

File: `os_config.h`

Defines the time interval in milliseconds between consecutive NTP server synchronization requests.

Valore: `64000U`

Note:
This value determines the frequency of network time updates. Increasing this value reduces network traffic and CPU overhead but may lead to larger clock drift between syncs. It depends on the network stack being initialized and the NTP client task being active. The value is an unsigned integer (U), typically set to 64000ms (64 seconds).

Uso:
Adjust this value if your application requires higher time precision (lower the value) or if you need to minimize bandwidth consumption (increase the value). Warning: Setting this value too low may flood the network or cause the NTP server to block your device; setting it too high may cause the system clock to drift significantly beyond acceptable tolerances for your application.

`NTP_PORT`

File: `caos/net/inc/net_proto.h`

Defines the UDP port number used for Network Time Protocol (NTP) synchronization.

Valore: `123U`

Note:

This constant sets the destination port for outgoing time sync requests and the listening port for incoming server responses. It must match the standard NTP port (123) to communicate with public or local time servers. Changing this value will prevent the system from synchronizing with standard NTP servers unless the server is specifically configured to listen on a non-standard port.

Uso:
Change this value only if your network architecture requires NTP traffic to be routed through a custom port or a proxy server. Ensure that your firewall settings and the target NTP server configuration are updated to match this value, otherwise, the system clock will fail to synchronize.

`NTP_RESPONSE_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum duration in milliseconds to wait for an NTP server response before timing out.

Valore: `5000U`

Note:
This constant determines the blocking duration for the network stack during time synchronization. If set too low, the system may fail to sync on high-latency networks. If set too high, it may delay system startup or task execution. The value is an unsigned integer, typically ranging from 1000 to 10000 depending on network stability.

Uso:
Increase this value if the device frequently fails to synchronize time due to poor network conditions or high latency. Decrease it if the system startup time is too slow and you are operating on a reliable, low-latency local network. Ensure the value is sufficient to account for round-trip time (RTT) plus server processing time.

`NTP_RETRY_BACKOFF_MS`

File: `os_config.h`

Defines the base time interval in milliseconds for the exponential backoff mechanism during NTP synchronization failures.

Valore: `10000U`

Note:
This value acts as the multiplier for the retry delay. When NTP requests fail, the system waits for (NTP_RETRY_BACKOFF_MS * 2^n) milliseconds before the next attempt, where 'n' is the number of consecutive failures. It must be a positive unsigned integer. Setting this too low may flood the network or the NTP server, while setting it too high increases the time required to recover from transient network outages.

Uso:
Adjust this value if your device operates on high-latency networks or if the NTP server enforces strict rate-limiting. Increase this value if you observe 'NTP sync failed' errors due to network congestion. Ensure this value is not set to zero to avoid immediate, rapid-fire retry loops that could crash the network stack.

`NTP_RETRY_N`

File: `os_config.h`

Defines the maximum number of attempts the system will make to synchronize time with an NTP server before failing.

Valore: `3U`

Note:
When enabled, the system attempts to reach the NTP server up to this count. If the value is set to 0, the system will not attempt any retries. Increasing this value improves reliability in unstable network environments but increases the total boot or sync time if the server is unreachable. Typical values range from 1 to 5.

Uso:
Increase this value if your device frequently logs 'NTP Sync Failed' errors during startup or periodic updates due to poor network connectivity. Decrease it if you need the system to fail fast and proceed to other tasks without waiting for network timeouts.

`NTP_SERVER_N`

File: `os_config.h`

Defines the maximum number of NTP server addresses stored in the system configuration.

Valore: `2U`

Note:
This constant determines the size of the internal array used to hold NTP server hostnames or IP addresses. Increasing this value allows the system to attempt synchronization with multiple time servers for redundancy. It must be a positive integer. If set to 0, NTP functionality may be disabled or restricted to a hardcoded default.

Uso:
Change this value when you need to add more fallback NTP servers to improve time synchronization reliability. Ensure that the memory allocated for the NTP client task is sufficient to handle the increased array size. Setting this value too high may lead to unnecessary memory consumption in the heap or static data section.

`OS_TICK_US`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the duration of a single system tick in microseconds, determining the OS heartbeat frequency.

Valori per MCU:

MCU	Valore
F103	CA_TICK_SPEED_2MS
F407	CA_TICK_SPEED_250US
F429	CA_TICK_SPEED_250US
F446	CA_TICK_SPEED_250US
F746	CA_TICK_SPEED_200US
H563	CA_TICK_SPEED_200US
H747	CA_TICK_SPEED_100US
H753	CA_TICK_SPEED_100US

Note:
This constant sets the resolution of the RTOS scheduler and software timers. Lower values (e.g., 100US) provide higher precision for task scheduling and timeouts but increase CPU overhead due to more frequent interrupt handling. It must be compatible with the hardware timer configuration. Typical values range from 100 to 2000 microseconds depending on the MCU performance class.

Uso:
Adjust this value to balance timing precision against CPU load. Increase the value if the system is overloaded by too many context switches. Decrease it only if your application requires high-resolution task execution or faster response times for software timers. Ensure all time-based logic in your application is scaled relative to this tick rate.

PACKET_TRACER_RING_SIZE

File: os_config.h

Defines the total number of slots available in the circular buffer used for packet tracing.

Valore: 8U

Note:
This constant determines the depth of the internal trace log. Increasing this value allows for a longer history of captured packets but consumes more RAM. It must be a power of two for optimal performance in the ring buffer logic. Typical values range from 4 to 64 depending on available heap memory.

Uso:
Increase this value if you are losing trace data during high-frequency communication bursts. Decrease it if the system is running low on static RAM. Ensure that the value is not set too high, as it may lead to stack overflow or memory exhaustion in resource-constrained STM32 devices.

PCLK1_FREQ_HZ

File: hw/f1xx/f103/objmap.h
File: hw/f4xx/f407/objmap.h
File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h
File: hw/h5xx/h563/objmap.h
File: hw/h7xx/h747/objmap.h
File: hw/h7xx/h753/objmap.h

Defines the operating frequency of the Peripheral Clock 1 (PCLK1) bus in Hertz.

Valori per MCU:

MCU	Valore
F103	36000000UL
F407	42000000UL
F429	42000000UL
F446	42000000UL
F746	54000000UL
H563	250000000UL
H747	100000000UL
H753	120000000UL

Note:
This constant is used by the RTOS kernel and peripheral drivers to calculate timing-dependent parameters such as baud rates, timer prescalers, and watchdog timeouts. It must match the actual hardware clock configuration set in the RCC registers. Incorrect values will cause communication errors (e.g., wrong UART baud rate) or incorrect timing intervals.

Uso:
Update this value whenever the system clock tree configuration (RCC) is modified. It is critical for ensuring that peripherals like UART, SPI, and Timers operate at the intended speeds. Always verify this value against the STM32 CubeMX clock configuration tab for your specific target MCU.

`PCLK2_FREQ_HZ`

File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the operating frequency of the Peripheral Clock 2 (PCLK2) bus in Hertz.

Valori per MCU:

MCU	Valore
F407	84000000UL
F429	84000000UL
F446	84000000UL
F746	108000000UL
H563	250000000UL
H747	100000000UL
H753	120000000UL

Note:
This constant informs the RTOS kernel and peripheral drivers of the exact clock speed of the APB2 bus. It is critical for calculating baud rates for UART, SPI, and timer prescalers. Values must match the actual hardware clock tree configuration set in the RCC registers. Incorrect values will lead to incorrect peripheral timing, such as garbled serial communication or wrong PWM frequencies.

Uso:

Update this value whenever the system clock tree (RCC) is modified in the hardware abstraction layer or startup files. If you change the PLL settings or the APB2 prescaler, you must recalculate and update this constant. Failure to keep this in sync with the hardware will cause peripheral drivers to malfunction, even if the CPU core itself appears to be running correctly.

`PCLK3_FREQ_HZ`

File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the operating frequency in Hertz of the Peripheral Clock 3 (PCLK3) bus for the specific STM32 microcontroller.

Valori per MCU:

MCU	Valore
H563	250000000UL
H747	100000000UL
H753	120000000UL

Note:
This constant is used by the RTOS kernel and peripheral drivers to calculate timing-dependent parameters such as baud rates, timer intervals, and watchdog timeouts. Enabling this ensures hardware peripherals attached to the APB3 bus operate at the correct speed. Values must match the actual hardware clock tree configuration defined in the System Clock Configuration (RCC). Typical values range from 50MHz to 250MHz depending on the specific STM32 series and PLL settings.

Uso:
Change this value only when modifying the system clock tree (e.g., changing the PLL multipliers or dividers in the RCC configuration). If this value is incorrect, peripheral communication (like UART, SPI, or I2C) will fail due to incorrect timing calculations, and RTOS software timers may drift significantly. Always verify this value against the STM32CubeMX clock configuration tool output.

`PCLK4_FREQ_HZ`

File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the operating frequency in Hertz of the Peripheral Clock 4 (PCLK4) bus for the STM32 MCU.

Valori per MCU:

MCU	Valore
H747	100000000UL
H753	120000000UL

Note:
This constant is used by the caOS hardware abstraction layer to calculate baud rates and timing intervals for peripherals connected to the APB4 bus. Enabling or changing this value directly affects the accuracy of communication interfaces like I2C, SPI, or timers mapped to this clock domain. It must match the actual clock tree configuration set in the System Clock Configuration (RCC) registers. Typical values are 100MHz for H747 and 120MHz for H753.

Uso:
Change this value only when modifying the system clock tree (e.g., changing the PLL settings or clock dividers). If this value is incorrect, peripherals on the APB4 bus will operate at the wrong speed, leading to communication errors, frame corruption, or timeout failures. Always verify this value against the STM32CubeMX clock configuration tool output.

`POOL_QUEUE_SIZE`

File: `os_config.h`

Defines the maximum number of message slots available in the system memory pool for inter-task communication.

Valore: `8`

Note:
This constant determines the total capacity of the global message queue. Increasing this value consumes more RAM from the heap. It must be greater than zero and is typically set to a power of two for optimal performance. If the queue fills up, tasks attempting to send messages will be blocked or return an error depending on the API call.

Uso:
Increase this value if your application experiences 'Queue Full' errors during high-traffic periods or when multiple tasks send messages simultaneously. Decrease it if your system is running low on RAM and you have verified that the current queue depth is never fully utilized.

`PRINTF`

File: `os_config.h`

Enables or disables the system-wide formatted output logging functionality via the ca_printf macro.

Valore: `ca_printf(STDOUT,BUFF,LEN,__VA_ARGS__)`

Note:
When enabled, this constant maps the standard printf-style calls to the caOS internal serial output driver. Disabling this flag removes the overhead of string formatting and buffer management, significantly reducing flash memory usage and CPU cycles. It depends on the UART/USART peripheral being initialized in the hardware abstraction layer.

Uso:
Enable this during development and debugging to monitor system state and task execution via a serial terminal. Disable this in production builds to save memory and prevent blocking the CPU with slow serial transmission. Ensure the buffer size (BUFF) is large enough to accommodate your longest log message, otherwise, output will be truncated.

`PRINTF_N`

File: `os_config.h`

Defines the macro used for system-wide formatted output logging.

Valore: `ca_printf_n(STDOUT,BUFF,LEN,__VA_ARGS__)`

Note:

This constant maps the standard printf functionality to the specific caOS output driver. Enabling or modifying this allows redirection of logs to UART, ITM, or memory buffers. It depends on the underlying hardware abstraction layer (HAL) being initialized. Typical values are function pointers or macros that wrap the hardware-specific transmit function.

Uso:
Change this value when porting the RTOS to new hardware or when switching the debug output interface (e.g., from UART to SWO). Ensure the provided function signature matches the expected arguments (STDOUT, buffer, length, and variadic arguments) to prevent memory corruption or hard faults during runtime logging.

`PSP_CHECK_TOP`

File: `caos/inc/mpu.h`

Enables or disables the stack overflow detection mechanism for the Process Stack Pointer (PSP).

Valore: `0`

Note:
When set to 1, the MPU (Memory Protection Unit) monitors the stack limit to trigger a fault if the stack pointer exceeds the defined boundary. When set to 0, this hardware-based protection is disabled. This flag requires the MPU to be initialized and configured in the system startup code. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag (set to 1) during development and debugging to catch stack overflow errors early, which otherwise cause silent memory corruption or hard faults. Disable it (set to 0) only if you need to save a negligible amount of CPU cycles or if your specific hardware configuration does not support MPU-based stack monitoring. Warning: disabling this makes the system vulnerable to undetected stack overflows.

`PUT`

File: `os_config.h`

A macro function used to send formatted debug messages or system logs to the standard output (STDOUT) interface.

Valore: `ca_put(STDOUT,MSG)`

Note:
This function acts as a wrapper for the system's serial or logging peripheral. Enabling it allows real-time monitoring of task execution and error reporting. It depends on the hardware abstraction layer (HAL) being initialized for the UART or ITM port. Typical usage involves passing a string literal or a formatted buffer. It is non-blocking in some configurations but may introduce latency if the output buffer is full.

Uso:
Use this during development to trace task transitions, interrupt triggers, or variable states. Change this value when switching between different debug interfaces (e.g., UART to SWO). Warning: Excessive use of ca_put within high-frequency tasks or critical sections can significantly degrade system performance and timing determinism; always remove or wrap in debug-only macros before deploying to production.

`PUT_N`

File: `os_config.h`

A macro used to output a specific message string to a designated system output stream.

Valore: `ca_put_n(STDOUT,MSG)`

Note:
This constant defines the interface for system logging or console output. When enabled, it routes messages to the hardware peripheral defined by STDOUT (e.g., UART or ITM). It depends on the underlying hardware abstraction layer (HAL) being initialized. Typical values are the macro definition itself, which wraps the system's low-level character transmission function.

Uso:
Change this value when redirecting system logs to a different peripheral, such as switching from UART1 to UART2 for debugging. Use this to solve issues where system status messages are not appearing on your terminal. Warning: Ensure the baud rate and hardware pins for the new STDOUT are correctly configured, or the system may hang while waiting for the transmission buffer to clear.

`RO_MPU_REGION`

File: `hw/h5xx/h563/objmap.h`

Defines the total number of hardware Memory Protection Unit (MPU) regions available for the caOS kernel to manage.

Valori per MCU:

MCU	Valore
`H563`	`15U`

Note:
This constant directly maps to the physical MPU hardware capabilities of the STM32H563. Setting this value higher than the hardware limit (15) will cause memory access faults or kernel initialization errors. It is a static configuration that dictates how many memory segments (e.g., Flash, RAM, Peripheral space) the RTOS can protect simultaneously.

Uso:
You should only change this value if you are porting the RTOS to a different STM32 chip with a different MPU architecture. For the H563, it must remain at 15U. Do not modify this value to 'solve' memory access errors; if you encounter a MemManage fault, check your task stack sizes or memory region definitions instead.

`SHA256_BLOCK_SIZE`

File: `caos/crypto/inc/sha256.h`

Defines the fixed byte length of a single data block processed by the SHA-256 hashing algorithm.

Valore: `64`

Note:
This constant is set to 64 bytes (512 bits) as per the FIPS 180-4 standard. It is a hard-coded requirement for the internal buffer size of the SHA-256 state machine. Changing this value

will cause the cryptographic functions to produce incorrect hashes or trigger memory access violations.

Uso:
Do not modify this value under any circumstances. It is defined by the SHA-256 specification. If you are implementing a custom crypto driver or buffer management, use this constant instead of hard-coding the number 64 to ensure code maintainability and compliance with the algorithm's requirements.

`SHA256_DIGEST_SIZE`

File: `caos/crypto/inc/sha256.h`

Defines the fixed output length in bytes for the SHA-256 cryptographic hash algorithm.

Valore: `32`

Note:
This constant is set to 32 bytes (256 bits) as per the SHA-256 standard. Changing this value will break the cryptographic implementation and cause buffer overflows or incorrect hash calculations. It is a read-only constant used for memory allocation in hash context structures.

Uso:
Do not modify this value. It is used to allocate static buffers for storing digest results. If you are implementing a function that handles SHA-256 outputs, always use this constant instead of hardcoding the number 32 to ensure code maintainability and prevent errors if the algorithm is ever swapped.

`SHA512_BLOCK_SIZE`

File: `caos/crypto/inc/sha512.h`

Defines the fixed byte length of a single data block processed by the SHA-512 hashing algorithm.

Valore: `128`

Note:
This constant is set to 128 bytes (1024 bits) as per the FIPS 180-4 standard for SHA-512. It is a hard-coded architectural requirement for the internal buffer size of the hashing engine. Changing this value will cause compilation errors or runtime memory corruption in the crypto stack, as it is tightly coupled with the SHA-512 state machine and padding logic.

Uso:
Do not modify this value. It is defined by the cryptographic standard and is not a tunable parameter. If you are implementing a custom crypto driver or buffer management system, use this constant to ensure your buffers are correctly sized to hold exactly one SHA-512 block.

`SHA512_DIGEST_SIZE`

File: `caos/crypto/inc/sha512.h`

Defines the fixed output length of the SHA-512 hashing algorithm in bytes.

Valore: `64`

Note:
This constant is set to 64 bytes (512 bits). It is a hard-coded requirement of the SHA-512 standard. Modifying this value will cause cryptographic signature verification failures and buffer overflows in functions expecting a 64-byte digest array.

Uso:
Do not change this value. It is used to allocate buffers for hash results. If you are writing code that stores SHA-512 hashes, always use this constant to define your array size (e.g., uint8_t hash[SHA512_DIGEST_SIZE]) to ensure compatibility and prevent memory corruption.

`SPINLOCK_FREE`

File: `caos/inc/atomic.h`

A configuration flag that determines whether the kernel uses hardware-based spinlocks for atomic operations.

Valore: `0`

Note:
When set to 0, the system enforces the use of hardware spinlocks to ensure thread safety during atomic operations. If set to 1, spinlocks are disabled, which may lead to race conditions in multi-core or preemptive environments. This flag is typically dependent on the underlying architecture's support for atomic instructions (e.g., LDREX/STREX on ARM Cortex-M).

Uso:
Set this to 0 in multi-threaded or multi-core applications to prevent data corruption. Only set this to 1 if you are running on a single-core system with interrupts disabled or if you are implementing a custom, non-blocking synchronization mechanism, as disabling it without proper alternatives will cause system instability.

`SPINLOCK_TAKEN`

File: `caos/inc/atomic.h`

A unique magic number used to identify the state of a spinlock as currently held by a processor core.

Valore: `0x08091961`

Note:
This constant is used as a sentinel value in atomic memory operations to verify lock ownership. It must be a unique 32-bit pattern that does not conflict with valid memory addresses or other status flags. Changing this value requires updating all assembly-level atomic primitives and the spinlock acquisition logic across the entire kernel.

Uso:
This value should generally not be changed. It is used for debugging and memory integrity checks during spinlock operations. If you are porting the RTOS to a new architecture or suspect memory corruption in the spinlock state, ensure this constant matches the value expected by the hardware-specific atomic instructions.

SPI_DEF_PKT_SIZE

File: caos/drivers/inc/spi.h

Defines the default size in bytes for SPI data packets when no specific length is provided.

Valore: 128U

Note:
This constant sets the buffer allocation size for SPI transactions. Increasing this value consumes more RAM in the SPI driver's internal buffers. It must be large enough to accommodate the largest expected data frame in your application. Typical values range from 16 to 256 depending on available heap memory.

Uso:
Adjust this value if you encounter buffer overflow errors during SPI transfers or if your peripheral requires larger data chunks. Ensure that the value does not exceed the available RAM allocated for the SPI driver, otherwise, the system may experience memory corruption or hard faults.

SSH_LISTEN_PORT

File: os_config.h

Defines the TCP port number on which the caOS SSH server listens for incoming remote connections.

Valore: 22U

Note:
This constant sets the listening socket port for the SSH daemon. The default value is 22, which is the standard IANA port for SSH. Valid values range from 1 to 65535. Ensure the chosen port does not conflict with other network services running on the STM32, such as HTTP (80) or Telnet (23).

Uso:
Change this value if you need to run the SSH server on a non-standard port for security through obscurity or to avoid port collisions in a specific network environment. Warning: Changing this to a port below 1024 may require specific privileges in some environments, and remote clients must be updated to connect to the new port number.

STACK_CANARY_SIZE

File: caos/inc/mpu.h

Defines the size in bytes of the memory protection guard zone added to each task stack to detect overflows.

Valore: 32

Note:
When enabled, the RTOS places a specific pattern at the end of the stack. If the stack pointer exceeds this boundary, the MPU triggers a fault. Increasing this value provides a larger buffer but consumes more RAM per task. It is typically set to 32 bytes, but must be a multiple of the MPU region alignment requirements (usually 32 or 64 bytes depending on the STM32 architecture).

Uso:

Increase this value if you suspect stack corruption or intermittent hard faults during heavy task execution. Decrease it only if you are extremely constrained by RAM and have verified stack usage via static analysis or runtime monitoring. Setting this to 0 disables stack overflow protection, which is strongly discouraged for production firmware.

`STACK_CANARY_VALUE`

File: `caos/inc/mpu.h`

A unique 64-bit pattern placed at the end of each task stack to detect memory corruption.

Valore: `0xCAFEBABEDEADBEEFULL`

Note:
When enabled, the kernel writes this specific hex value to the stack boundary. If the value is overwritten, the system triggers a stack overflow exception. It requires the MPU (Memory Protection Unit) to be active. The value must be a 64-bit constant to ensure alignment and uniqueness.

Uso:
Change this value only if you suspect a collision with legitimate data patterns in your application memory. Use this to debug 'HardFault' errors caused by stack overflows. Do not disable this in production, as it is a critical safety mechanism for detecting buffer overruns.

`STACK_FILL_PATTERN`

File: `caos/inc/scheduler.h`

The hexadecimal byte pattern used to initialize task stack memory areas upon creation.

Valore: `0xDEADC0DE`

Note:
When a task is created, the RTOS fills its allocated stack space with this specific pattern. This allows the system to track stack usage by checking how much of this pattern has been overwritten by function calls and local variables. It has no functional impact on task execution but is critical for debugging stack overflows. The value must be a 32-bit word.

Uso:
Change this value if you need to distinguish stack memory from other initialized data in your debugger's memory view. It is primarily used during development to identify stack depth; if you see the pattern at the very bottom of the stack, you are at risk of a stack overflow. Do not change this value unless you have a specific reason to track memory patterns differently in your IDE.

`STACK_MIN`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`

File: `hw/h7xx/h753/objmap.h`

Defines the absolute minimum stack size in bytes allowed for any task created within the caOS RTOS.

Valori per MCU:

MCU	Valore
F103	256
F407	512
F429	512
F446	512
F746	512
H563	2048
H747	2048
H753	2048

Note:
This constant acts as a safety floor for task memory allocation. If a task is created with a stack size smaller than STACK_MIN, the kernel will either reject the task creation or force the size to this value. Higher values are required for architectures with larger register sets or deeper interrupt nesting (e.g., H7 series). It is strictly dependent on the specific MCU architecture's memory footprint and stack frame requirements.

Uso:
Increase this value if you encounter stack overflow errors or hard faults during task initialization. Do not decrease this value below the recommended architecture default, as it will lead to unpredictable system crashes and memory corruption. Ensure that your task stack sizes are always a multiple of 8 bytes to maintain proper alignment on ARM Cortex-M processors.

`STDOUT_ON_ITM`

File: `os_config.h`

Enables or disables the redirection of standard output (printf) to the ARM Cortex-M ITM (Instrumentation Trace Macrocell) peripheral.

Valore: `0`

Note:
When set to 1, the system routes stdout data through the ITM stimulus port 0, allowing real-time logging via an external debugger like ST-LINK. When set to 0, this feature is disabled, and stdout will not produce output via ITM. This requires the debugger's SWO pin to be connected and configured in your IDE's debug settings.

Uso:
Enable this (set to 1) during development when you need to monitor system logs or debug messages without using a physical UART peripheral. Disable it (set to 0) for production builds to save CPU cycles and avoid potential blocking behavior if the debugger is not connected.

`STDOUT_ON_LPUART`

File: `os_config.h`

Enables or disables the redirection of standard output (printf) to the LPUART peripheral.

Valore: `0`

Note:
When set to 1, the system initializes the LPUART hardware and routes all standard output streams to it. When set to 0, standard output is disabled or redirected to a null device. This flag depends on the LPUART peripheral being correctly configured in the hardware abstraction layer. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Set this to 1 during development to enable serial debugging and log messages via the LPUART interface. Set to 0 in production builds to save power and reduce CPU overhead caused by string formatting and UART transmission. Ensure the baud rate and GPIO pins are correctly initialized before enabling this flag to avoid system hangs during initialization.

`STDOUT_ON_UART`

File: `os_config.h`

Enables or disables the redirection of standard output (printf) to the hardware UART peripheral.

Valore: `1`

Note:
When set to 1, the system routes stdout to the configured UART port; when 0, stdout is disabled or redirected to a null device. This flag depends on the UART driver being initialized in the board support package. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Enable this during development to view debug logs via a serial terminal. Disable it in production builds to save CPU cycles and reduce power consumption, or if the UART pins are required for other communication protocols.

`STDOUT_ON_USB_CDC`

File: `os_config.h`

Enables or disables the redirection of standard output (printf) to the USB CDC virtual COM port.

Valore: `0`

Note:
When set to 1, the system initializes the USB peripheral and routes stdout to the host PC via USB. When set to 0, stdout is disabled or routed to the default UART peripheral. This flag requires the USB_DEVICE_ENABLED flag to be set to 1. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Change this to 1 when you need to debug your application using a terminal emulator on your PC via USB. Set it to 0 if you are using UART for logging or if you need to save power by disabling the USB stack. Ensure your USB hardware is connected and the driver is installed on the host PC before enabling.

`STDOUT_QUEUE_DEPTH`

File: `caos/inc/stdout.h`

Defines the maximum number of characters that can be buffered in the STDOUT output queue before blocking or dropping data.

Valore: `64`

Note:
This constant sets the size of the circular buffer used by the system's standard output stream. If the buffer fills up faster than the hardware peripheral (e.g., UART) can transmit, subsequent print calls may block or lose data depending on the driver implementation. It must be a positive integer, typically a power of two for optimal performance. Increasing this value consumes more RAM but reduces the likelihood of output stalls during high-frequency logging.

Uso:
Increase this value if you notice truncated log messages or if your application performs heavy logging that causes the system to hang. Decrease this value if your device is running low on SRAM. Ensure that the value is large enough to hold the longest single log message you intend to print to avoid partial output.

`SVC_OS_END`

File: `caos/inc/safeguard.h`

A magic constant used by the caOS kernel to identify the end of a Supervisor Call (SVC) sequence.

Valore: `0xFD`

Note:
This value is typically used in the context of system call handling or kernel-level state transitions. It acts as a sentinel or marker in the stack frame or register set during an SVC exception. It is a fixed internal constant (0xFD) and should not be modified by application code. It is tightly coupled with the low-level assembly implementation of the caOS context switcher.

Uso:
This constant is for internal kernel use only. Do not change this value. Modifying it will break the kernel's ability to correctly identify and return from system calls, likely resulting in a hard fault or system hang. If you are debugging and see this value in a register or stack dump, it indicates the processor is currently processing an OS-level service request.

`SVC_SAFEGUARD`

File: `caos/inc/safeguard.h`

A magic constant used to verify the integrity of the Supervisor Call (SVC) stack frame during context switches.

Valore: `0xFE`

Note:
When enabled, the kernel checks this value at the base of the stack to detect stack overflows or memory corruption. If the value does not match 0xFE, the system triggers a kernel panic. This

flag must be consistent across all task stack initializations and is dependent on the architecture-specific SVC handler implementation.

Uso:
Change this value only if you are porting caOS to a new architecture or if you need to avoid a collision with specific hardware-reserved memory patterns. Do not modify this value during runtime; incorrect values will cause the system to enter a hard fault or kernel panic immediately upon the first task switch.

`SYSCLK_FREQ_HZ`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the target system clock frequency in Hertz for the MCU core.

Valori per MCU:

MCU	Valore
F103	72000000UL
F407	168000000UL
F429	168000000UL
F446	168000000UL
F746	216000000UL
H563	250000000UL
H747	400000000UL
H753	480000000UL

Note:
This constant is used by the RTOS kernel to calculate timing intervals, tick rates, and peripheral baud rates. It must match the actual hardware clock configuration set in the RCC registers. Setting this value incorrectly will cause all time-dependent functions (like delays, timeouts, and UART communication) to run at the wrong speed. Valid values are strictly determined by the specific STM32 model's maximum operating frequency.

Uso:
Change this value only when modifying the system clock tree (e.g., changing the PLL settings or external crystal frequency). Always ensure this value matches the frequency calculated in your clock configuration code. If your system timing seems 'slow' or 'fast' compared to real-time, verify this constant first.

`SYSLOG_FAC_KERN`

File: `caos/net/inc/net_proto.h`

Defines the facility code for kernel-level messages in the system logging protocol.

Valore: `0U`

Note:

This constant sets the 'facility' field in syslog packets to 0, identifying the source as the kernel. It is used by the network logging stack to categorize messages. Changing this value will cause log aggregators to misclassify kernel events as coming from other system components (e.g., mail or user processes). It must remain 0 to comply with standard RFC 5424 logging conventions for kernel logs.

Uso:
Do not modify this value unless you are implementing a custom logging protocol that requires non-standard facility mapping. Changing this will break log filtering and severity analysis on remote syslog servers.

`SYSLOG_FAC_LOCAL0`

File: `caos/net/inc/net_proto.h`

Defines the syslog facility identifier for local use 0, used to categorize network log messages.

Valore: `16U`

Note:
This constant sets the facility field in the syslog header to 16. It is used by the network stack to tag outgoing log packets. It has no direct impact on system performance but requires the remote syslog server to be configured to accept messages from the 'local0' facility.

Uso:
Change this value only if your network infrastructure requires a specific syslog facility code (e.g., local1 through local7) to route logs to different files or servers. Ensure the value matches the standard syslog facility definitions (0-23) to avoid malformed log headers.

`SYSLOG_FAC_LOCAL7`

File: `caos/net/inc/net_proto.h`

Defines the syslog facility code for local use 7 (value 23) used in network logging protocols.

Valore: `23U`

Note:
This constant maps to the standard Syslog facility 'local7' as defined in RFC 5424. It is used to categorize log messages sent over the network. Changing this value will cause log collectors (like rsyslog or syslog-ng) to misclassify or ignore incoming logs from the device. It has no direct impact on RTOS scheduling or memory, but it must match the configuration of your remote logging server.

Uso:
Change this value only if your network infrastructure requires a specific facility code for log filtering or routing. Use this when you need to separate device logs from other system logs on a centralized server. Ensure the value remains within the valid syslog facility range (0-23) to avoid protocol violations.

`SYSLOG_FAC_USER`

File: `caos/net/inc/net_proto.h`

Defines the facility code for user-level messages in the system logging protocol.

Valore: `1U`

Note:
This constant sets the 'facility' field in a syslog packet to the 'USER' category (value 1). It is used by the network stack to categorize logs generated by application-level tasks. It must be a valid integer defined by the RFC 5424 standard; changing this value may cause log servers to misclassify or ignore incoming messages.

Uso:
Change this value only if your network logging infrastructure requires a specific facility code other than the standard 'USER' category. Ensure that your remote syslog server is configured to accept and process the facility code you assign here, otherwise, your application logs may be filtered out or lost.

`SYSLOG_MSG_MAX`

File: `os_config.h`

Defines the maximum character length allowed for a single system log message.

Valore: `128U`

Note:
This constant sets the buffer size for the internal logging queue. If a message exceeds 128 bytes, it will be truncated. Increasing this value consumes more RAM from the system heap, while decreasing it saves memory but risks losing data in long diagnostic strings.

Uso:
Increase this value if you notice your debug logs are being cut off mid-sentence. Decrease it only if your STM32 device is running extremely low on RAM. Ensure that the buffer size is large enough to accommodate your longest 'printf' style debug statements.

`SYSLOG_PORT`

File: `caos/net/inc/net_proto.h`

Defines the UDP port number used for transmitting system log messages over the network.

Valore: `514U`

Note:
This constant sets the destination port for the caOS logging subsystem. It typically defaults to 514, which is the standard port for the Syslog protocol (RFC 5424). Changing this value requires the receiving log server to be configured to listen on the new port. It is a dependency for the network logging module; if the network stack is disabled, this value is ignored.

Uso:
Change this value only if your network infrastructure requires logs to be sent to a non-standard port or if there is a port conflict with other network services. Ensure the value is a valid 16-bit unsigned integer (1-65535). Setting this to an invalid or occupied port will result in log packets being dropped or rejected by the network stack.

`SYSLOG_QUEUE_SIZE`

File: `os_config.h`

Defines the maximum number of log messages that can be stored in the system log queue before new messages are dropped.

Valore: `8U`

Note:
This value determines the depth of the internal message buffer for the system logger. Increasing this value consumes more RAM but prevents log loss during high-frequency bursts. It must be a positive integer, typically a power of two for optimal performance. If set too low, the system may experience 'log overflow' errors when multiple tasks attempt to write logs simultaneously.

Uso:
Increase this value if you notice missing log entries during high-load scenarios or complex interrupt sequences. Decrease it if your application is running low on heap memory. Ensure that the task processing the log queue is fast enough to keep up with the rate of incoming messages to avoid filling the buffer.

`SYSLOG_SEV_ALERT`

File: `caos/net/inc/net_proto.h`

Defines the severity level for system alert messages within the caOS network logging subsystem.

Valore: `1U`

Note:
This constant represents the numerical priority level for 'Alert' events. It is used by the logging filter to determine if a message should be recorded or transmitted. It typically ranges from 0 to 7, where lower values indicate higher urgency. It depends on the global SYSLOG_LEVEL_THRESHOLD setting; if the system threshold is set higher than 1, these alerts may be suppressed.

Uso:
Change this value only if you are modifying the core network protocol logging architecture. It is used to categorize critical network failures that require immediate attention. Do not change this value to filter logs; instead, adjust the system-wide logging threshold to avoid missing critical system alerts.

`SYSLOG_SEV_CRIT`

File: `caos/net/inc/net_proto.h`

Defines the numerical severity level for critical system log messages within the caOS networking stack.

Valore: `2U`

Note:
This constant sets the threshold for logging; when enabled, only messages with a severity level equal to or greater than 2 are recorded. It is typically used in conjunction with the global logging verbosity filter. Valid values are integers, where lower numbers represent higher urgency.

Uso:
Change this value if you need to filter out non-critical network logs to save memory or reduce UART/buffer traffic. Do not set this value too high during debugging, as you may lose visibility into critical system failures or stack overflows occurring within the network protocol layer.

SYSLOG_SEV_DEBUG

File: `caos/net/inc/net_proto.h`

Sets the minimum severity level for system log messages to include debug-level information.

Valore: `7U`

Note:
When enabled, the system logs all messages with a severity level of 7 or lower. Disabling or increasing this value reduces memory usage and CPU overhead by filtering out verbose debug logs. It depends on the global logging subsystem being initialized and requires sufficient buffer space in the log queue.

Uso:
Change this value during development to troubleshoot network protocol issues by enabling detailed trace logs. Set it to a lower value (e.g., 3 for errors only) in production environments to prevent log buffer overflows and minimize performance impact.

SYSLOG_SEV_EMERG

File: `caos/net/inc/net_proto.h`

Defines the numerical severity level for emergency system logs, representing the highest priority error state.

Valore: `0U`

Note:
This constant is used as a filter or identifier in the caOS logging subsystem. Setting this to 0U indicates that the message is critical and the system is likely unusable. It is typically used in conjunction with a bitmask or threshold check; if the system log level is set to 0, only emergency messages will be recorded.

Uso:
Do not change this value as it is part of the standard syslog protocol definition (RFC 5424). Use this constant when calling the logging API to report catastrophic hardware failures or kernel panics that require immediate attention.

SYSLOG_SEV_ERR

File: `caos/net/inc/net_proto.h`

Defines the severity level threshold for system error logging in the network stack.

Valore: `3U`

Note:
This constant sets the minimum severity level required for a network event to be recorded in the system log. A value of 3U typically corresponds to 'Error' level messages. Decreasing this

value increases log verbosity, while increasing it filters out less critical warnings. It depends on the global logging subsystem being initialized.

Uso:
Change this value during debugging to capture more granular network diagnostic information. Set it to a higher value in production environments to reduce memory usage and CPU overhead caused by excessive logging. Ensure the value remains within the range defined by the system's logging enumeration to avoid undefined behavior.

`SYSLOG_SEV_INFO`

File: `caos/net/inc/net_proto.h`

Defines the severity level threshold for system logging, specifically set to informational messages.

Valore: `6U`

Note:
This constant sets the logging filter level to 6. When enabled, the system will record all messages with a severity level of 6 (INFO) or higher (more critical). Decreasing this value increases the volume of logs, while increasing it filters out less critical information. It depends on the global logging subsystem being initialized.

Uso:
Change this value when you need to debug network protocol behavior without flooding the log buffer with low-level debug data. Use it during integration testing to monitor standard operational events. Warning: setting this value too low in a production environment may cause performance degradation due to excessive UART or flash memory write operations.

`SYSLOG_SEV_NOTICE`

File: `caos/net/inc/net_proto.h`

Defines the severity level for 'Notice' messages in the caOS system logging framework.

Valore: `5U`

Note:
This constant represents a numerical severity level of 5. It is used by the logging subsystem to filter messages; only logs with a severity equal to or higher than the configured system threshold will be processed or transmitted. It is typically used in conjunction with other severity constants like SYSLOG_SEV_ERROR or SYSLOG_SEV_DEBUG.

Uso:
Change this value only if you are modifying the core logging protocol definitions. It is used as a reference point for log filtering logic. Do not change this value if you are simply trying to adjust the verbosity of your application logs; instead, adjust the global system log level threshold in your configuration header.

`SYSLOG_SEV_WARN`

File: `caos/net/inc/net_proto.h`

Defines the severity level threshold for system logging, specifically targeting warning-level events.

Valore: `4U`

Note:
This constant sets the filter level for the caOS logging subsystem. When enabled, the system will record events with a severity of 4 or higher. Lowering this value increases log verbosity, while raising it filters out less critical messages. It depends on the global SYSLOG_LEVEL configuration and typically ranges from 0 (Emergency) to 7 (Debug).

Uso:
Change this value when you need to debug network protocol issues without flooding the log buffer with informational messages. Increase the threshold (e.g., to 5 or 6) in production environments to reduce memory usage and CPU overhead caused by excessive logging, or decrease it during development to capture potential warning signs before they escalate into system errors.

`SYSTICK_ERROR`

File: `caos/inc/systick.h`

A sentinel value representing a failure in the system timer initialization or operation.

Valore: `-1`

Note:
This constant is typically returned by the caOS kernel initialization functions when the hardware timer fails to start. It is not a configurable setting but a status code. It depends on the HAL_SYSTICK_Config function success. The value -1 is used to indicate an error state in signed integer return types.

Uso:
Use this constant to check the return value of system initialization functions. If a function returns SYSTICK_ERROR, the RTOS kernel cannot guarantee timing accuracy, and the system should enter a safe state or trigger a hardware reset. Do not modify this value as it is a reserved error code.

`SYSTICK_OK`

File: `caos/inc/systick.h`

A configuration flag that enables or disables the internal caOS System Tick timer driver.

Valore: `0`

Note:
When set to 1, the RTOS initializes the hardware timer to generate periodic interrupts for task scheduling. When set to 0, the Systick driver is disabled, meaning the kernel will not have a time base for preemptive multitasking or delay functions. This flag must be enabled for any RTOS features requiring time-slicing or blocking delays.

Uso:
Set this to 1 for standard RTOS operation. Set to 0 only if you are implementing a custom time-base driver or if you are running the system in a bare-metal mode where the RTOS scheduler is not required. Disabling this while using RTOS primitives like vTaskDelay will cause the system to hang or behave unpredictably.

`TASK_CANARY_VALUE_SAFE`

File: `caos/inc/scheduler.h`

A unique 32-bit pattern used to detect stack overflows by filling unused stack memory.

Valore: `0xCACAFEFC`

Note:
When enabled, the kernel writes this value to the entire stack area during task creation. The system periodically checks if this value has been overwritten, indicating a stack overflow. It requires sufficient RAM to store the canary pattern and depends on the stack monitoring feature being active in the kernel configuration.

Uso:
Change this value only if it conflicts with specific memory patterns used by your application code. Use this to debug hard faults caused by stack corruption. Warning: Do not set this to 0x00000000 or 0xFFFFFFFF, as these are common values in uninitialized memory and will lead to false negatives in overflow detection.

`TASK_CANARY_VALUE_SAFE_FP`

File: `caos/inc/scheduler.h`

The specific 32-bit pattern used to detect stack overflows in task memory regions.

Valore: `0xCACAFEFD`

Note:
When enabled, the kernel writes this value to the entire stack area of a task upon creation. During context switches, the scheduler checks if the top of the stack still contains this value. If the value is corrupted, the system triggers a stack overflow fault. This constant must be a 32-bit word aligned with the architecture's word size. It has no direct dependencies on other flags but requires sufficient stack space to be allocated to avoid false positives.

Uso:
Change this value only if you suspect memory corruption patterns are conflicting with the default constant. It is primarily used for debugging stack usage; if your system crashes with a stack overflow error, verify that your task stack sizes are large enough. Do not set this to a value that is likely to appear naturally in your application's data, as it will mask potential stack overflows.

`TASK_CANARY_VALUE_STD`

File: `caos/inc/scheduler.h`

The default 32-bit pattern used to fill task stacks to detect stack overflows.

Valore: `0xCACAFEF8`

Note:
When enabled, the kernel writes this specific hex value across the entire stack memory area of a task during creation. If the stack pointer exceeds the allocated bounds, the kernel checks if this pattern has been overwritten. It requires the stack monitoring feature to be enabled in the kernel configuration. The value 0xCACAFEF8 is chosen because it is unlikely to occur naturally in program data.

Uso:
Change this value only if you need to avoid specific memory patterns that might conflict with your application's data or if you are performing advanced debugging. Ensure the value is a 32-bit word aligned with the architecture. If you change this, you must also update the corresponding check logic in the kernel's stack overflow handler.

`TASK_CANARY_VALUE_STD_FP`

File: `caos/inc/scheduler.h`

The default 32-bit pattern used to fill task stacks to detect stack overflows.

Valore: `0xCACAFEF9`

Note:
When enabled, the kernel writes this specific hex value across the entire stack memory area of a task during creation. If the stack pointer exceeds the allocated bounds, the kernel checks if this pattern has been overwritten. This constant must be a 32-bit word aligned value. Changing this value requires a full project rebuild to ensure all stack initialization routines use the new pattern.

Uso:
Change this value if you suspect the default pattern (0xCACAFEF9) is accidentally appearing in your application data, causing false-positive stack overflow detections. Use a unique, non-zero value that is unlikely to occur naturally in your program's variables. Ensure the value is defined as a 32-bit unsigned integer to maintain memory alignment and prevent bus faults during stack initialization.

`TASK_NAME_LEN`

File: `caos/inc/scheduler.h`

Defines the maximum number of characters allowed for a task name string.

Valore: `12`

Note:
This constant sets the fixed size of the character array used to store task identifiers in the Task Control Block (TCB). If set to 12, names longer than 11 characters (plus the null terminator) will be truncated. Increasing this value increases the memory footprint of every task created in the system.

Uso:
Adjust this value if your project requires more descriptive task names for debugging or logging purposes. Ensure that the value is large enough to accommodate your naming convention, but keep it as small as possible to conserve RAM, especially in systems with a high number of concurrent tasks.

`TCP_ARP_TIMEOUT_MS`

File: `os_config.h`

Defines the duration in milliseconds that the system waits for an ARP response before timing out.

Valore: `2000U`

Note:
This constant determines the lifespan of an ARP request packet. If set too low, the system may fail to resolve IP addresses to MAC addresses on busy networks. If set too high, it increases latency when communicating with new devices. The value is typically set between 1000 and 5000 milliseconds depending on network stability.

Uso:
Increase this value if you experience frequent 'Host Unreachable' errors or connection timeouts on high-latency or congested networks. Decrease it only if your application requires rapid failure detection for non-responsive network nodes. Ensure this value is consistent with the overall network stack timeout settings to avoid race conditions.

`TCP_CLOSE_WAIT_MS`

File: `os_config.h`

Defines the timeout duration in milliseconds for a TCP connection to remain in the CLOSE_WAIT state.

Valore: `10000U`

Note:
This constant determines how long the stack waits for the application to acknowledge a connection closure before forcing a reset. It is dependent on the system tick frequency. Typical values range from 5000U to 30000U depending on network latency requirements.

Uso:
Increase this value if you experience premature connection resets during slow application processing. Decrease it if you need to free up socket resources faster in high-traffic environments. Setting this too low may cause active connections to drop unexpectedly.

`TCP_CONNECT_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits for a TCP connection to be established.

Valore: `5000U`

Note:
This constant sets the timeout duration for the socket connect operation. If the connection is not completed within this period, the function returns a timeout error. It depends on the underlying network stack's tick rate. Typical values range from 1000U to 10000U depending on network latency requirements.

Uso:
Increase this value if you are connecting to remote servers over high-latency networks or unstable connections to prevent premature timeouts. Decrease it if you need the application to fail fast when a server is unreachable to maintain system responsiveness. Setting this too low may cause connection failures on busy networks.

`TCP_FLAG_ACK`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the Acknowledgment (ACK) field in a TCP packet header.

Valore: `0x10U`

Note:
When set, this flag indicates that the Acknowledgment Number field in the TCP header is valid. It is a fundamental component of the TCP state machine, used to confirm receipt of data segments. This constant is typically used in conjunction with bitwise OR operations to construct or parse TCP headers. It has no direct dependencies on other flags but must be used in accordance with the TCP protocol specification (RFC 793).

Uso:
Use this flag when manually constructing TCP packets or when inspecting incoming packet headers to determine if the segment is an acknowledgment. Do not modify the value 0x10U, as it is defined by the TCP protocol standard. Incorrect usage or failure to set this flag when required will result in dropped connections or retransmission loops.

`TCP_FLAG_FIN`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the TCP FIN (Finish) control bit used to signal the graceful termination of a connection.

Valore: `0x01U`

Note:
This flag is set in the TCP header control field. When enabled, it indicates that the sender has no more data to transmit. It is typically used in conjunction with the TCP state machine to transition from ESTABLISHED to FIN_WAIT_1 or CLOSE_WAIT states. It has no dependencies on other flags but must be handled by the TCP stack's state transition logic.

Uso:
Change this value only if you are modifying the low-level TCP/IP stack implementation or debugging packet headers. Do not modify this constant for application-level code. Using an incorrect value will cause the TCP stack to misinterpret connection termination requests, leading to hung sockets or broken network communication.

`TCP_FLAG_PSH`

File: `caos/net/inc/net_proto.h`

Defines the PUSH flag in the TCP header to force immediate data delivery to the application layer.

Valore: `0x08U`

Note:
When set, this flag instructs the receiving TCP stack to push buffered data to the application immediately rather than waiting for the buffer to fill. It is a single-bit flag within the TCP control byte. It has no direct dependencies on other flags but must be used in conjunction with valid sequence numbers.

Uso:
Enable this flag when sending time-sensitive control packets or the final segment of a data stream to reduce latency. Do not set this flag on every single packet in a high-throughput stream, as it can cause excessive interrupt overhead and degrade network performance by preventing efficient packet coalescing.

`TCP_FLAG_RST`

File: `caos/net/inc/net_proto.h`

A control flag used in the TCP header to indicate an immediate connection reset.

Valore: `0x04U`

Note:
When this flag is set in a TCP packet, the receiving stack must immediately abort the connection and discard all associated buffers. It is a bitmask value (0x04U) typically combined with other TCP flags. It has no dependencies on other RTOS flags but requires the network stack to be in a valid state to process the reset signal.

Uso:
Use this flag when you need to force-close a connection due to an error, a timeout, or an invalid packet sequence. Do not set this flag manually unless you are implementing custom low-level socket handling, as incorrect usage will cause unexpected connection drops and potential data loss for the peer.

`TCP_FLAG_SYN`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the Synchronize sequence number control bit in a TCP packet header.

Valore: `0x02U`

Note:
This flag is used during the TCP three-way handshake to initiate a connection. When set to 0x02, the TCP stack interprets the segment as a connection request. It is typically used in conjunction with other flags like ACK or FIN. It must be defined as 0x02 to comply with RFC 793 standards for TCP header formatting.

Uso:
Change this value only if you are implementing a custom or non-standard TCP stack variant. For standard network communication, this value should remain unchanged. Incorrect values will cause the remote host to reject connection attempts or fail to recognize the packet type, leading to silent connection timeouts.

`TCP_FLAG_URG`

File: `caos/net/inc/net_proto.h`

A bitmask flag representing the Urgent pointer field in a TCP packet header.

Valore: `0x20U`

Note:

When set in the TCP control bits, this flag indicates that the Urgent Pointer field in the TCP header is valid and contains data that should be processed with higher priority. It is typically used in conjunction with the TCP_URG_PTR field. This flag is a standard part of the TCP protocol stack and should not be modified unless implementing custom protocol extensions.

Uso:
Use this flag when inspecting or constructing TCP segments that require out-of-band data signaling. It is primarily used for urgent data transmission, such as interrupting a remote process. Do not manually set this flag unless you are handling specific legacy protocols or specialized network traffic, as incorrect usage can lead to unexpected behavior in standard TCP/IP stacks.

`TCP_MAX_CONN`

File: `os_config.h`

Defines the maximum number of concurrent TCP connections allowed by the caOS network stack.

Valore: `8U`

Note:
This constant determines the size of the internal connection control block (CCB) table. Increasing this value consumes more RAM (each connection requires a fixed memory buffer for state tracking). It must be greater than 0 and is typically limited by the available heap memory. If set too low, new connection requests will be rejected by the stack.

Uso:
Adjust this value based on your application's memory constraints and the expected number of simultaneous clients. Increase it if your device acts as a server handling multiple concurrent requests; decrease it to save RAM if the device only communicates with a single master node.

`TCP_MAX_INFLIGHT`

File: `os_config.h`

Defines the maximum number of unacknowledged TCP segments allowed in the network buffer.

Valore: `16U`

Note:
This constant controls the TCP sliding window size at the transport layer. Increasing this value allows higher throughput on high-latency links but consumes more RAM per socket. It must be balanced against the total available heap memory and the number of concurrent active connections. Typical values range from 4 to 32.

Uso:
Increase this value if you observe slow data transfer speeds or high packet loss on high-bandwidth networks. Decrease this value if the system experiences memory allocation failures (heap exhaustion) during heavy network traffic. Ensure that the total memory allocated for all sockets does not exceed the system's available RAM.

`TCP_MAX_LISTEN`

File: `os_config.h`

Defines the maximum number of pending TCP connection requests that can be queued for a listening socket.

Valore: `2U`

Note:
This constant determines the size of the backlog queue for the TCP stack. Increasing this value allows the system to handle more simultaneous incoming connection attempts before rejecting new ones. It consumes additional RAM for each slot in the queue. Valid range is typically 1 to 16, depending on available heap memory.

Uso:
Increase this value if your application experiences 'Connection Refused' errors during high-traffic periods or when multiple clients attempt to connect simultaneously. Decrease it if the system is running low on memory. Setting this too high may lead to memory exhaustion if many clients attempt to connect at once.

`TCP_MAX_RETRIES`

File: `os_config.h`

Defines the maximum number of times the TCP stack will attempt to retransmit a packet before declaring a connection failure.

Valore: `5U`

Note:
When enabled, the stack will retry sending unacknowledged segments up to this count. Increasing this value improves reliability on lossy networks but increases the time taken to detect a broken connection. It depends on the TCP_RETRANSMIT_TIMEOUT setting. Typical values range from 3 to 10; setting this too high may cause the application to hang while waiting for a timeout.

Uso:
Increase this value if your device experiences frequent packet loss or intermittent connectivity issues that cause premature socket closures. Decrease it if you need the system to detect and recover from network failures faster. Ensure this value is balanced with your application's latency requirements.

`TCP_MSS_DEFAULT`

File: `caos/net/inc/net_proto.h`

Defines the Maximum Segment Size (MSS) in bytes for TCP connections, representing the largest amount of data that can be received in a single TCP segment.

Valore: `1460U`

Note:
This value directly impacts the TCP payload size. Enabling a larger value increases throughput by reducing header overhead, while a smaller value may be required for networks with specific MTU constraints. It is typically set to 1460 to fit within a standard 1500-byte Ethernet MTU

after accounting for IP and TCP headers. It must be less than or equal to the network interface MTU minus 40 bytes.

Uso:
Adjust this value if your device communicates over networks with restricted MTU sizes (e.g., VPNs, tunnels, or specific cellular links) to prevent packet fragmentation. Setting this value too high relative to the network path MTU will cause packet loss or performance degradation due to fragmentation; setting it too low will unnecessarily increase protocol overhead.

`TCP_RTO_INITIAL_MS`

File: `os_config.h`

Defines the initial Retransmission Timeout (RTO) value in milliseconds for new TCP connections.

Valore: `1000U`

Note:
This value sets the duration the stack waits for an acknowledgment before retransmitting the first SYN packet. Increasing this value helps in high-latency networks, while decreasing it speeds up connection failure detection. It must be a positive integer, typically ranging from 200 to 3000 depending on the expected network stability.

Uso:
Adjust this value if you experience frequent connection timeouts on slow or congested networks. If set too low, the system may trigger unnecessary retransmissions, wasting bandwidth; if set too high, the system will be slow to recover from dropped packets during the initial handshake.

`TCP_RTO_MAX_MS`

File: `os_config.h`

Defines the maximum timeout duration in milliseconds for a TCP retransmission attempt.

Valore: `16000U`

Note:
This constant sets the upper bound for the exponential backoff algorithm used during packet loss. If the system fails to receive an ACK within this period, the connection is typically dropped. It depends on the TCP_MAX_RETRIES setting; increasing this value allows for more robust connections on high-latency or unstable networks but increases the time taken to detect a dead link.

Uso:
Increase this value if your device operates on high-latency networks (e.g., satellite or congested cellular links) to prevent premature connection termination. Decrease it only if your application requires rapid detection of broken connections. Setting this value too low may cause frequent, unnecessary connection drops on busy networks.

`TCP_RX_RING_DEPTH`

File: `os_config.h`

Defines the number of packet slots available in the TCP receive buffer ring.

Valore: `4U`

Note:
This value determines how many incoming TCP segments can be queued before the stack begins dropping packets or applying backpressure. Increasing this value consumes more RAM (each slot is fixed-size based on MTU). It must be a power of two for optimal performance in the circular buffer implementation. Typical range is 2 to 16 depending on available heap memory.

Uso:
Increase this value if you observe packet loss or 'TCP receive buffer overflow' errors during high-throughput network bursts. Decrease this value if the system is running low on RAM and the network traffic is low-frequency or strictly request-response based.

`TCP_TCP_ACCEPT_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits for an incoming TCP connection request before aborting.

Valore: `10000U`

Note:
This constant controls the blocking duration of the accept() function. If set to 0, the system waits indefinitely. If the value is too low, legitimate clients may fail to connect during network congestion. It depends on the underlying TCP/IP stack's tick rate and memory availability for socket buffers.

Uso:
Increase this value if your application experiences frequent 'connection timeout' errors in high-latency network environments. Decrease it if you need the system to remain responsive and quickly free up resources when a client fails to initiate a handshake. Ensure the value is sufficient to cover the round-trip time of your network infrastructure.

`TCP_TIMER_TICK_MS`

File: `os_config.h`

Defines the time interval in milliseconds for the TCP/IP stack's internal timer heartbeat.

Valore: `100U`

Note:
This constant determines the resolution of TCP retransmissions, keep-alive probes, and connection timeouts. Decreasing this value increases the frequency of stack processing, which improves responsiveness but consumes more CPU cycles. It must be a multiple of the system tick period. Typical values range from 50ms to 500ms.

Uso:
Adjust this value if you experience slow connection recovery or delayed timeouts. Use a smaller value for high-speed networks requiring fast retransmission, or a larger value to reduce CPU

overhead in low-power applications. Setting this too low may cause the stack to starve other tasks of processing time.

`TCP_TIME_WAIT_MS`

File: `os_config.h`

Defines the duration in milliseconds that a TCP connection remains in the TIME_WAIT state after closure.

Valore: `4000U`

Note:
This constant controls how long the socket remains reserved after a connection is closed to ensure delayed packets are handled. Increasing this value consumes more memory resources as the socket control block cannot be reused until the timer expires. The default value is 4000ms (4 seconds).

Uso:
Increase this value if you experience data corruption or connection errors due to late-arriving packets from a previous session. Decrease it only if your system is running out of available sockets and you are certain that network latency is low enough to avoid packet collisions.

`TFTP_BLOCK_SIZE`

File: `caos/net/inc/tftp_service.h`

Defines the size in bytes of a single data packet transferred during a TFTP operation.

Valore: `512U`

Note:
This value directly impacts the payload size of UDP packets sent over the network. While 512 bytes is the standard defined by RFC 1350, increasing this value can improve throughput on high-speed networks, provided the underlying network stack and hardware buffers support larger MTUs. Decreasing it may be necessary for memory-constrained systems or unstable links, but values larger than 512 may cause compatibility issues with standard TFTP clients.

Uso:
Adjust this value if you encounter packet fragmentation issues or if you need to optimize file transfer speeds. Ensure that your network buffer size (defined elsewhere in the stack) is large enough to accommodate this value plus the UDP/IP/Ethernet header overhead. Do not change this unless you have verified that both the client and server support the chosen block size.

`TFTP_BLOCK_TIMEOUT_MS`

File: `os_config.h`

Defines the maximum time in milliseconds the system waits for a response during a TFTP data block transfer.

Valore: `5000U`

Note:
This constant sets the timeout duration for the TFTP client state machine. If no acknowledgment is received from the server within this period, the transfer is aborted. It depends on

the network latency and the reliability of the connection. Typical values range from 1000ms to 10000ms depending on the network environment.

Uso:
Increase this value if you experience frequent 'timeout' errors on high-latency or congested networks. Decrease it if you need the system to fail fast and recover quickly during a network disconnection. Setting this value too low may cause premature termination of valid transfers on slow links.

`TFTP_ERR_ACCESS`

File: `caos/net/inc/tftp_service.h`

An error code indicating that the TFTP server has denied access to the requested file or directory.

Valore: `2U`

Note:
This constant is returned by the TFTP service layer when a client attempts to read or write a file that violates security permissions or is outside the allowed root directory. It is a standard TFTP error code (Error Code 2) defined in RFC 1350. It does not depend on other flags but requires the file system abstraction layer to be correctly initialized.

Uso:
Use this value when implementing custom file access control logic within the TFTP callback functions. Do not modify this value, as it must remain compliant with the TFTP protocol specification to ensure compatibility with standard TFTP clients.

`TFTP_ERR_DISKFULL`

File: `caos/net/inc/tftp_service.h`

Error code indicating that the TFTP server cannot write data because the storage medium is full.

Valore: `3U`

Note:
This constant is returned by the TFTP service layer when a file write operation fails due to insufficient disk space. It is a specific error enumeration used in the TFTP packet response. It depends on the underlying filesystem driver reporting a 'disk full' status to the network stack.

Uso:
Use this value when implementing custom error handling or logging for TFTP file transfers. Do not modify this value as it must remain compliant with the TFTP protocol error code definitions (RFC 1350). If you see this error frequently, check the filesystem capacity or the file size limits of the storage partition.

`TFTP_ERR_EXISTS`

File: `caos/net/inc/tftp_service.h`

Error code indicating that the file requested for creation already exists on the server.

Valore: `6U`

Note:
This constant is returned by the TFTP service layer when a write request (WRQ) is received for a filename that is already present in the file system. It is a standard TFTP error code (Error Code 6) as defined in RFC 1350. It does not require configuration but must be handled by the client-side logic to prevent accidental overwriting of existing data.

Uso:
Use this constant in your application-level error handling switch-case blocks when implementing TFTP file transfer clients. If you receive this error, you should prompt the user or the automated system to either choose a different filename or explicitly delete the existing file before attempting the upload again.

`TFTP_ERR_ILLEGAL`

File: `caos/net/inc/tftp_service.h`

An error code indicating that the TFTP request received by the server is not supported or violates the protocol format.

Valore: `4U`

Note:
This constant represents the 'Illegal TFTP Operation' error defined in RFC 1350. When returned, the TFTP service will send an error packet to the client and terminate the current transfer session. It is a read-only status code used internally by the caOS network stack and should not be modified by the user.

Uso:
This value is used for debugging network communication issues. If you see this error in your logs, it typically means the TFTP client is sending malformed packets, using an unsupported transfer mode (e.g., requesting 'mail' mode instead of 'octet'), or attempting an operation that the caOS TFTP server does not implement.

`TFTP_ERR_NOTFOUND`

File: `caos/net/inc/tftp_service.h`

Error code returned by the TFTP service when a requested file does not exist on the storage medium.

Valore: `1U`

Note:
This constant is used as a return value in the TFTP protocol handler. It indicates that the server successfully processed the request but could not locate the specified filename. It is typically used in conjunction with the TFTP error packet mechanism (Error Code 1).

Uso:
Do not modify this value as it is defined by the TFTP protocol specification (RFC 1350). Use this constant in your application logic when checking the return status of file system read operations to distinguish between 'file not found' and other hardware or permission errors.

`TFTP_ERR_NOUSER`

File: `caos/net/inc/tftp_service.h`

Error code indicating that the requested TFTP user or account does not exist on the server.

Valore: `7U`

Note:
This is a constant value (7U) used within the TFTP protocol stack to signal an authentication or authorization failure. It is returned by the TFTP service layer when a client attempts to access a resource associated with a non-existent user. It does not affect system memory or scheduling, but acts as a return status for error handling logic.

Uso:
This value should not be changed as it is defined by the TFTP protocol specification (RFC 1350). Use this constant in your application code when implementing custom file access control or user validation logic to ensure compatibility with standard TFTP clients. If you receive this error, verify the user credentials or the file path mapping configured in the TFTP service.

`TFTP_ERR_TID`

File: `caos/net/inc/tftp_service.h`

Defines the specific error code returned by the TFTP service when an unexpected Transfer Identifier (TID) is received.

Valore: `5U`

Note:
This constant is used to identify packets originating from an unknown or unauthorized source port during an active TFTP session. When enabled, the stack compares the incoming packet's TID against the session's expected TID. If they do not match, the system triggers this error code. It is a standard protocol requirement for security and session integrity. The value 5U is the protocol-defined error code for 'Unknown transfer ID'.

Uso:
Do not change this value unless you are implementing a custom, non-standard TFTP variant. Changing this constant will cause the TFTP client to fail to recognize the error, potentially leading to session hangs or security vulnerabilities where unauthorized packets could interfere with an active file transfer.

`TFTP_ERR_UNDEF`

File: `caos/net/inc/tftp_service.h`

Represents a generic or undefined error condition within the TFTP service state machine.

Valore: `0U`

Note:
This constant is used as a fallback error code when a specific protocol violation or network failure does not map to a defined TFTP error type. It is typically returned by the TFTP server task when an unexpected packet structure or internal state mismatch occurs. It does not require specific dependencies but should be handled by the client-side error logging mechanism.

Uso:

This value should not be modified as it is part of the standard TFTP error enumeration. It is used by developers to identify 'catch-all' failure scenarios during debugging. If you encounter this error frequently, check for network packet corruption or incomplete TFTP request frames.

`TFTP_MAX_XFER`

File: `os_config.h`

Defines the maximum number of concurrent TFTP transfer sessions allowed by the caOS TFTP service.

Valore: `2U`

Note:
This constant controls the memory allocation for the TFTP server's internal session table. Increasing this value allows more simultaneous file transfers but consumes more RAM. It is typically set to a small integer (e.g., 2U to 4U) to conserve resources on embedded STM32 targets. It must be defined before initializing the TFTP service via ca_tftp_service_init.

Uso:
Increase this value if your application requires multiple simultaneous TFTP clients to upload or download files. Decrease it if you encounter memory allocation failures or if the system has very limited RAM. Ensure that the total memory footprint of all concurrent sessions does not exceed the available heap.

`TFTP_PORT`

File: `caos/net/inc/tftp_service.h`

Defines the UDP port number used by the caOS TFTP server for file transfer operations.

Valore: `69U`

Note:
This constant sets the listening port for incoming TFTP requests. The default value is 69, which is the IANA-registered port for TFTP. Changing this value requires all TFTP clients to be configured to connect to the new port. It must be a valid 16-bit unsigned integer (1-65535).

Uso:
Change this value only if your network environment requires a non-standard port to avoid conflicts with other services or to bypass specific firewall restrictions. Ensure that the new port is not already reserved by other system services or protocols to prevent binding failures.

`TFTP_RETRY_N`

File: `os_config.h`

Defines the maximum number of times the TFTP client will attempt to retransmit a packet before declaring a timeout error.

Valore: `3U`

Note:
Increasing this value allows the system to tolerate more packet loss on unstable networks but increases the total time taken to report a failed transfer. It depends on the TFTP_TIMEOUT_MS

setting; if the timeout is too short, high retry counts may still fail. Typical values range from 3 to 10 depending on network reliability.

Uso:
Increase this value if you experience frequent 'Transfer Failed' errors during firmware updates over lossy or congested Ethernet links. Do not set this value to 0, as it will disable retransmission entirely, causing the transfer to fail on the first dropped packet.

`TLS_HS_BUF_SIZE`

File: `caos/net/inc/tls.h`

Defines the size in bytes of the internal buffer used for TLS handshake operations.

Valore: `4096U`

Note:
This constant allocates a static memory block for the TLS handshake state machine. Increasing this value allows for larger certificate chains or more complex handshake parameters, but consumes more RAM. Decreasing it may cause handshake failures if the peer sends large certificate chains that exceed the buffer capacity. Typical value is 4096 bytes, which is generally sufficient for standard TLS 1.2/1.3 handshakes.

Uso:
Adjust this value if you encounter 'TLS handshake failed' errors when connecting to servers with large certificate chains. Ensure the value is a multiple of the system's memory alignment requirements. If your system is low on RAM, you may attempt to reduce this value, but be aware that it will limit the maximum size of the handshake messages the device can process.

`TLS_MAX_PLAINTEXT`

File: `caos/net/inc/tls.h`

Defines the maximum size in bytes of a single TLS plaintext record fragment.

Valore: `16384U`

Note:
This constant sets the upper limit for the TLS record layer buffer. Increasing this value allows for larger data chunks per TLS packet, potentially improving throughput for large transfers, but it directly increases the RAM footprint of every active TLS connection. The value 16384 is the standard maximum defined by the TLS specification (RFC 5246).

Uso:
Change this value if you are working on a memory-constrained device and need to reduce RAM usage by lowering the maximum TLS record size. Warning: reducing this value below 16384 may cause compatibility issues with some TLS peers that expect the full standard buffer size. Ensure your heap allocation is sufficient to handle the chosen size multiplied by the number of concurrent TLS connections.

`TLS_READ_CLOSED`

File: `caos/net/inc/tls.h`

A constant representing the error state when a TLS connection has been closed by the remote peer.

Valore: `(-1)`

Note:
This value is returned by ca_tls_read when the underlying socket or TLS session has been gracefully terminated. It is a negative integer (-1), which is standard for indicating an error or EOF condition in network APIs. It does not indicate a hardware failure, but rather a protocol-level closure.

Uso:
Use this constant when checking the return value of ca_tls_read. If the function returns TLS_READ_CLOSED, you should stop attempting to read from that connection and proceed to call ca_tls_close to release the associated resources. Do not treat this as a fatal error; it is the expected behavior when a client or server disconnects.

`TLS_READ_ERROR`

File: `caos/net/inc/tls.h`

Error code indicating a failure during a TLS read operation.

Valore: `(-2)`

Note:
This constant is returned by ca_tls_read when the underlying secure socket fails to retrieve data. It typically signifies a connection reset, a protocol violation, or a timeout at the TLS layer. It is a negative integer (-2), consistent with other error codes in the caOS network stack.

Uso:
Use this value to check the return status of ca_tls_read. If the function returns TLS_READ_ERROR, the application should assume the secure session is no longer reliable and should proceed to close the connection using ca_tls_close and potentially attempt a reconnection.

`TLS_READ_TIMEOUT`

File: `caos/net/inc/tls.h`

Defines the default timeout in milliseconds for TLS read operations.

Valore: `0`

Note:
This constant determines how long the system waits for incoming TLS data before returning an error. A value of 0 typically indicates an infinite timeout (blocking indefinitely). This setting affects the behavior of ca_tls_read. It is a global configuration and does not depend on other flags, but it should be balanced against the system's watchdog requirements to prevent task starvation.

Uso:
Change this value if your application experiences unexpected hangs during network communication or if you need to enforce a strict deadline for data reception. If set to 0, ensure that the calling task has a mechanism to handle potential permanent blocks, such as a watchdog or a separate monitoring thread. Use a non-zero value if you want the system to recover gracefully from network drops or unresponsive peers.

`TLS_RX_BUF_SIZE`

File: `caos/net/inc/tls.h`

Defines the total memory buffer size allocated for incoming TLS data packets.

Valore: `(5U + TLS_MAX_PLAINTEXT + 256U)`

Note:
The value is calculated as 5 bytes (TLS record header) + TLS_MAX_PLAINTEXT (maximum payload size) + 256 bytes (overhead for MAC and padding). Increasing this value consumes more RAM per TLS connection. It must be large enough to accommodate the maximum expected TLS record size; otherwise, incoming packets will be truncated or rejected.

Uso:
Adjust this value if you encounter TLS handshake failures or data corruption when receiving large packets. If your application uses small, fixed-size messages, you may decrease this to save RAM, provided it remains larger than the largest expected TLS record. Ensure the system has sufficient heap memory before increasing this constant.

`TLS_TX_BUF_SIZE`

File: `caos/net/inc/tls.h`

Defines the total size of the TLS transmission buffer in bytes.

Valore: `(5U + TLS_TX_RECORD + 1U + 16U)`

Note:
This constant calculates the memory allocation required for outgoing TLS packets. It accounts for the TLS record header (TLS_TX_RECORD), protocol overhead (5U), padding/-MAC (16U), and a safety margin (1U). It is a static memory allocation; increasing this value directly increases the RAM footprint of every TLS connection context.

Uso:
Adjust this value only if you encounter 'buffer too small' errors during TLS transmission or if you need to optimize RAM usage on memory-constrained STM32 devices. Ensure that the resulting size is sufficient to hold the maximum application payload plus the TLS overhead. Incorrectly low values will cause ca_tls_write to fail or truncate data.

`TLS_TX_RECORD`

File: `caos/net/inc/tls.h`

Defines the maximum size in bytes for a single TLS record transmission buffer.

Valore: `2048U`

Note:
This constant allocates memory for the TLS transmission buffer. Increasing this value allows for larger TLS packets, which can improve throughput for large data transfers but increases the static memory footprint of every TLS connection. Decreasing it saves RAM but may cause fragmentation of large application messages into multiple TLS records, increasing overhead. Typical values are powers of 2, such as 1024, 2048, or 4096.

Uso:

Adjust this value if you encounter 'buffer too small' errors during TLS communication or if you need to optimize RAM usage on memory-constrained devices. Ensure the value is sufficient to hold the maximum expected application payload plus TLS header and MAC overhead. Do not set this value excessively high to avoid exhausting the system heap.

`UART_DBG_BAUDRATE`

File: `os_config.h`

Defines the communication speed in bits per second for the system debug UART interface.

Valore: `CA_UART_BAUD_115200`

Note:
This constant sets the baud rate for the hardware peripheral used for logging and shell commands. It must match the baud rate configured on your terminal emulator (e.g., PuTTY, Tera Term). Valid values are standard baud rates like 9600, 57600, or 115200. Ensure the system clock frequency is high enough to support the requested baud rate with minimal error percentage.

Uso:
Change this value if you experience garbled text in your serial console or if you need to increase throughput for high-frequency logging. Always ensure the hardware connection (TX/RX lines) is stable before increasing the baud rate, as higher speeds are more susceptible to signal noise.

`UART_DBG_NUM`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Specifies the hardware UART peripheral index used for system-wide debug logging and console output.

Valori per MCU:

MCU	Valore
F103	1
F407	1
F429	3
F446	3
F746	3
H563	3
H747	1
H747	3
H753	3

Note:
This constant maps the caOS logging subsystem to a specific physical UART instance (e.g., 1 for USART1, 3 for USART3). Enabling this flag routes all system diagnostic messages to the selected peripheral. It depends on the hardware availability of the specific STM32 MCU variant;

selecting an invalid index will result in a hard fault or silent failure during initialization. Typical values range from 1 to 6 depending on the MCU datasheet.

Uso:
Change this value when porting the firmware to a different STM32 board or when the default debug pins are required for other application functions. Ensure the selected UART is correctly initialized in the hardware abstraction layer (HAL) and that the baud rate matches your terminal settings. Warning: setting this to an incorrect index will disable all debug output, making system troubleshooting significantly more difficult.

`UART_DBG_PINMAP`

File: `caos/drivers/inc/uart.h`

Defines the hardware pin mapping configuration for the debug UART interface.

Valore: `0U`

Note:
This constant selects which physical GPIO pins are assigned to the debug UART peripheral. Setting this to 0U typically selects the default hardware mapping (e.g., PA9/PA10 on many STM32 series). Changing this value requires a corresponding update to the hardware schematic and potentially the GPIO initialization code. It has no direct impact on RTOS scheduling but is critical for serial communication stability.

Uso:
Change this value only when moving the debug console to a different set of pins on the MCU to avoid pin conflicts with other peripherals. Ensure the selected pins support the UART alternate function in the datasheet. Incorrect values will result in no serial output or potential electrical shorts if the pins are configured for conflicting functions.

`UART_STDOUT_NUM`

File: `hw/h7xx/h747/objmap.h`

Specifies the hardware UART peripheral index used for system standard output (printf/logging).

Valori per MCU:

MCU	Valore
H747	1
H747	3

Note:
This constant maps the RTOS logging stream to a specific physical UART port on the STM32. For the H747, valid values are typically 1 or 3, corresponding to USART1 or USART3. Enabling this requires the corresponding GPIO pins and UART peripheral to be initialized in the hardware abstraction layer. If set to an invalid index, system logs will be silently dropped or may cause a hard fault if the peripheral clock is not enabled.

Uso:
Change this value when you need to route debug messages to a different physical connector on your development board. Use 1 if you are using the primary ST-Link virtual COM port or 3 if your specific hardware design routes the console to a different header. Ensure the chosen UART

is not being used by another application task to avoid data corruption or transmission conflicts.

`UDPCLI_MAX_HANDLES`

File: `os_config.h`

Defines the maximum number of concurrent UDP client handles allowed in the caOS network stack.

Valore: `4U`

Note:
This constant determines the size of the internal static memory pool allocated for UDP client structures. Increasing this value consumes more RAM (SRAM) but allows more simultaneous UDP connections. It must be greater than zero and is limited by the available heap or static memory defined in the system linker script.

Uso:
Increase this value if your application requires more simultaneous UDP communication channels (e.g., multiple logging servers or telemetry streams). If you set this value too high, the system may fail to compile or trigger a hard fault due to memory exhaustion. Ensure that the total number of handles does not exceed the hardware's network buffer capacity.

`UDPCLI_RING_DEPTH`

File: `os_config.h`

Defines the maximum number of pending UDP packets that can be stored in the input ring buffer before the system starts dropping new incoming data.

Valore: `4U`

Note:
This value determines the memory allocation for the UDP command line interface buffer. Increasing this value allows the system to handle larger bursts of incoming UDP traffic but consumes more RAM. It must be a power of two for optimal performance in most caOS implementations. Typical values range from 2 to 16 depending on available heap memory.

Uso:
Increase this value if you observe packet loss during high-frequency UDP communication or when the system is busy processing other tasks. Decrease this value if the system is running low on RAM. Setting this value too high may lead to heap exhaustion, while setting it too low will cause the UDP interface to become unresponsive under load.

`UDPSRV_MAX_CLIENTS`

File: `os_config.h`

Defines the maximum number of concurrent UDP client connections supported by the caOS network stack.

Valore: `4U`

Note:

This constant determines the size of the internal connection tracking table. Increasing this value consumes more RAM (each client requires a dedicated control block). It must be set to a value greater than 0. Typical values range from 1 to 16 depending on available heap memory and application requirements.

Uso:
Increase this value if your application needs to handle more simultaneous UDP streams or if you receive 'connection table full' errors. Decrease it to save RAM if your system only communicates with a single master controller or a limited number of peers.

`UDPSRV_RING_DEPTH`

File: `os_config.h`

Defines the number of slots in the UDP server's circular buffer for incoming packets.

Valore: `8U`

Note:
Each slot holds one UDP packet structure. Increasing this value consumes more RAM but allows the system to buffer more incoming packets during traffic bursts. It must be a power of two for optimal performance in the ring buffer logic. Typical range is 4 to 32 depending on available heap memory.

Uso:
Increase this value if the system is dropping UDP packets during high-frequency network traffic. Decrease it if the application is running low on RAM. Ensure that the processing task is fast enough to clear the buffer, otherwise, increasing the depth only delays the inevitable overflow.

`UDPSRV_WORKER_STACK_MIN`

File: `caos/net/inc/udp_server.h`

Defines the minimum stack size in bytes allocated for each UDP server worker thread.

Valore: `2048U`

Note:
This value determines the memory footprint of every spawned UDP worker task. If set too low, the system will trigger a stack overflow exception during complex packet processing. It must be a multiple of the architecture's word size (typically 4 or 8 bytes). Increasing this value consumes more RAM from the heap or static pool, while decreasing it saves memory but risks stability.

Uso:
Increase this value if your UDP server handles complex protocols, performs deep function calls, or uses large local buffers within the worker callback. Decrease it only if RAM is extremely limited and you have verified via stack watermarking that the current usage is significantly lower than 2048 bytes. Always perform stress testing after modifying this value to ensure no stack corruption occurs.

`UNUSED`

File: `caos/inc/common.h`

A macro used to explicitly mark a variable as intentionally unused to prevent compiler warnings.

Valore: `((void)(x))`

Note:
When enabled, the compiler ignores the variable during static analysis, preventing 'unused variable' warnings. It has no effect on the final binary size or execution speed as it evaluates to a void cast. It is typically used in callback functions or API implementations where a parameter is required by the function signature but not needed by the logic.

Uso:
Use this macro whenever you have a function parameter that you do not intend to use in your code. This keeps your build logs clean and ensures that legitimate warnings are not hidden by 'noise'. Do not use this on variables that are intended to be used, as it will mask potential logic errors where a variable was forgotten.

`USB_BCD_DEVICE`

File: `caos/usb/inc/usb_mgmt.h`

Defines the Binary Coded Decimal (BCD) version number of the USB device.

Valore: `0x0100U`

Note:
This value represents the USB specification version the device complies with (e.g., 0x0100 for USB 1.0, 0x0200 for USB 2.0). It is reported to the host during the USB enumeration process via the Device Descriptor. Changing this value does not change the physical hardware capabilities, only the version reported to the operating system.

Uso:
Update this value to match the USB standard your hardware implementation is designed to support. If the host OS expects a higher version than what is reported, it may trigger compatibility warnings or fail to load specific drivers. Ensure the value is formatted as a 16-bit BCD integer (e.g., 0x0200 for version 2.0.0).

`USB_CDC_EP_DATA`

File: `caos/usb/inc/usb_cdc.h`
File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the hardware endpoint index used for USB CDC data transmission and reception.

Valori per MCU:

MCU	Valore
F103	1U
F407	1U
F429	1U
F446	1U
F746	3U
H563	3U
H747	3U
H753	3U

Note:
This constant specifies the physical endpoint number assigned to the CDC data interface. Enabling a higher value allows the USB stack to map the data stream to a specific hardware buffer. It is strictly dependent on the USB peripheral architecture of the STM32 series; for example, F1/F4 series typically use endpoint 1, while H7/H5 series require endpoint 3. Incorrect values will result in USB enumeration failure or silent data loss.

Uso:
Change this value only when porting the caOS USB stack to a different STM32 MCU family. Do not modify this value for standard application development. Setting an invalid endpoint index will cause the USB host to reject the device or fail to open the virtual COM port.

`USB_CDC_EP_NOTIF`

File: `caos/usb/inc/usb_cdc.h`
File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the endpoint address used for USB CDC interrupt notifications.

Valori per MCU:

MCU	Valore
F103	2U
F407	2U
F429	2U
F446	2U
F746	4U
H563	4U
H747	4U
H753	4U

Note:
This constant specifies the hardware endpoint index for the CDC notification pipe. Enabling this allows the host to receive asynchronous status updates from the device. It is strictly tied to the USB peripheral's hardware capabilities; values must match the specific MCU's USB controller architecture (e.g., 2U for F4 series, 4U for H7 series). Incorrect values will cause USB enumeration failure or silent data transmission errors.

Uso:
Change this value only when porting the caOS USB stack to a new STM32 family or when reconfiguring the USB descriptor table. Ensure the value matches the hardware endpoint allocation defined in the MCU reference manual. Setting an invalid endpoint index will result in the USB stack failing to initialize the notification interface, preventing the host from detecting serial state changes.

`USB_CDC_FIFO_WORDS_DATA`

File: `caos/usb/inc/usb_cdc.h`

Defines the size of the USB CDC receive buffer in 32-bit words.

Valore: `64U`

Note:
This constant determines the memory allocation for the CDC data FIFO. The total buffer size in bytes is calculated as (USB_CDC_FIFO_WORDS_DATA * 4). Increasing this value allows the system to buffer more incoming data during high-traffic periods, reducing the risk of buffer overflows, but it consumes more RAM. It must be a positive integer, typically a power of two for optimal memory alignment.

Uso:
Adjust this value if you experience data loss during high-speed serial communication. If the application processes incoming USB data slowly, increase this value to provide a larger safety margin. Conversely, if your STM32 device is low on RAM, you may decrease this value, provided the data throughput remains manageable.

`USB_CDC_FIFO_WORDS_NOTIF`

File: `caos/usb/inc/usb_cdc.h`

Defines the size of the USB CDC notification FIFO buffer in 32-bit words.

Valore: `8U`

Note:
This constant determines the depth of the internal queue used to store CDC state change notifications (e.g., serial line state, break signals). Increasing this value allows the system to buffer more events during high-traffic periods, preventing data loss. It must be a positive integer, typically a power of two for optimal performance. It depends on the USB stack's event processing speed; if the application processes notifications slower than they arrive, this buffer will overflow.

Uso:
Increase this value if you observe dropped CDC notifications or 'FIFO overflow' errors in the USB debug logs during heavy serial communication. Decrease it only if you are extremely constrained by RAM, as setting this too low can cause the USB stack to miss critical state changes from the host.

`USB_DFU_ATTR_CAN_DNLOAD`

File: `caos/usb/inc/usb_dfu.h`

A bitmask flag indicating that the DFU device supports firmware download operations.

Valore: `0x01U`

Note:
When set to 0x01, the DFU descriptor informs the host that the device is capable of receiving new firmware images. If this bit is cleared, the host will treat the device as read-only, preventing any firmware update attempts. This flag is a mandatory component of the DFU functional descriptor and must be consistent with the actual implementation of the DFU_DNLOAD request handler in the application layer.

Uso:
Enable this flag when you want to allow users to update the device firmware via USB. You should only disable this if the device is intended to be strictly read-only or if the DFU interface is being used solely for status reporting. Incorrectly setting this flag while the backend code lacks download support will result in the host attempting to send data that the device will reject, potentially causing the host-side DFU tool to report an error.

`USB_DFU_ATTR_CAN_UPLOAD`

File: `caos/usb/inc/usb_dfu.h`

A bitmask flag indicating that the DFU device supports uploading (reading) firmware from the device memory to the host.

Valore: `0x02U`

Note:
When this bit is set in the DFU functional descriptor, the host is notified that the device supports the DFU_UPLOAD request. If disabled, the host will typically grey out or disable the 'Read' or 'Extract' functionality in DFU tools like dfu-util. This flag is usually combined with other attributes using a bitwise OR operation.

Uso:
Enable this flag if you want to allow users to back up or verify the firmware currently running on the STM32. Disable it if you need to protect intellectual property or prevent firmware extraction for security reasons. Ensure your DFU implementation actually handles the DFU_UPLOAD state machine requests before setting this flag, otherwise, the host may encounter errors during read attempts.

`USB_DFU_ATTR_MANIFEST_TOL`

File: `caos/usb/inc/usb_dfu.h`

Defines the DFU manifest tolerance attribute for the USB device descriptor.

Valore: `0x04U`

Note:
This flag sets the bit 2 of the DFU attributes field, indicating that the device can communicate during the manifest phase. When enabled, the host expects the device to remain responsive after a download; if disabled, the host assumes the device will reset immediately. It must be consistent with the device's firmware update implementation and the DFU class specification.

Uso:
Change this value if the host-side DFU tool reports timeout errors or fails to verify the firmware after the download phase. Set this to 0x04U if your application requires the device to perform

post-download processing (like internal flash verification) before resetting. Ensure the host-side driver supports this attribute to avoid communication stalls.

`USB_DFU_ATTR_WILL_DETACH`

File: `caos/usb/inc/usb_dfu.h`

A bitmask flag indicating that the USB device will perform a self-detach sequence before entering DFU mode.

Valore: `0x08U`

Note:
When this bit is set in the DFU functional descriptor, the host expects the device to disconnect and reconnect automatically after receiving a DFU_DETACH request. If disabled, the host may wait indefinitely for a disconnect that never happens. This flag is typically ORed with other attributes in the bmAttributes field of the DFU descriptor.

Uso:
Enable this flag when your application firmware needs to trigger a software reset or jump to the bootloader automatically upon a DFU request. If you disable this, you must manually disconnect and reconnect the USB cable or toggle the D+ pull-up resistor to force the host to re-enumerate the device in DFU mode.

`USB_DFU_STR_IFACE`

File: `caos/usb/inc/usb_dfu.h`

Defines the string descriptor index for the USB Device Firmware Upgrade (DFU) interface.

Valore: `4U`

Note:
This constant sets the index value used by the USB host to identify the DFU interface string in the device descriptor table. It must match the index defined in the USB string descriptor array. Changing this value requires a corresponding update in the string descriptor table to avoid enumeration errors or incorrect interface labeling in the OS.

Uso:
Change this value only if you are modifying the USB descriptor structure or if there is a conflict with other USB interface string indices. Ensure the value is unique among all interface descriptors to prevent host-side identification issues. Incorrect values will cause the DFU interface to fail to initialize or appear with an incorrect name in the device manager.

`USB_DFU_XFER_MAX`

File: `caos/usb/inc/usb_dfu.h`

Defines the maximum size in bytes for a single USB Device Firmware Upgrade (DFU) data transfer packet.

Valore: `64U`

Note:
This constant sets the buffer size used during DFU firmware download operations. The value 64U is standard for Full-Speed USB endpoints. Increasing this value requires matching support

in the host-side DFU tool and the underlying USB hardware endpoint configuration. If set too high, it may cause buffer overflows or USB transaction errors.

Uso:
Change this value only if you are optimizing DFU transfer speeds and have verified that the USB hardware endpoint descriptors and the host-side DFU software can handle larger packet sizes. For most standard STM32 implementations, 64 bytes is the optimal and safest value.

`USB_EP0_MPS`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the Maximum Packet Size (MPS) in bytes for the USB Endpoint 0 (Control Endpoint).

Valori per MCU:

MCU	Valore
F103	64U
F407	64U
F429	64U
F446	64U
F746	64U
H563	64U
H747	64U
H753	64U

Note:
This constant sets the buffer size for the initial handshake and enumeration phase of the USB device. For Full-Speed USB, the standard value is 64 bytes. Changing this value affects the hardware peripheral's internal FIFO allocation. It must match the value defined in the USB Device Descriptor to avoid enumeration failures or data corruption.

Uso:
Change this value only if you are implementing a custom USB stack or working with a specific hardware requirement that deviates from the USB 2.0 Full-Speed specification. Setting this to a value other than 64 on standard STM32 hardware will likely cause the host computer to fail to recognize the device during the initial enumeration process.

`USB_EP0_TX_BUF`

File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the size in bytes of the transmission buffer for USB Endpoint 0.

Valori per MCU:

MCU	Valore
H747	512U
H753	512U

Note:
This constant determines the maximum packet size the device can send during the control transfer phase. For STM32H7 series microcontrollers, the value is typically set to 512 bytes to match the hardware FIFO capacity. Changing this value requires a corresponding update in the USB descriptor tables; if the buffer size is smaller than the requested data length, the USB stack may fail to enumerate or cause data corruption.

Uso:
Adjust this value only if you are modifying the USB hardware abstraction layer or implementing custom USB classes that require specific buffer alignment. For standard HID or CDC implementations on H747/H753, keep this at 512U. Setting this value too low will cause the host to report a device malfunction, while setting it higher than the physical FIFO size will lead to memory overflows.

`USB_EP0_XFR_MAX`

File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the maximum transfer size in bytes for the USB Control Endpoint 0 (EP0).

Valori per MCU:

MCU	Valore
H747	127U
H753	127U

Note:
This constant sets the buffer limit for EP0 data transactions. For STM32H7 series microcontrollers, the value is fixed at 127U to align with the hardware FIFO constraints and USB specification requirements for control transfers. Disabling or modifying this value outside the recommended range will likely cause USB enumeration failures or data corruption during the setup phase.

Uso:
This value should generally not be changed by the user. It is configured to ensure the USB stack correctly handles standard requests during device enumeration. If you encounter 'USB Device Not Recognized' errors or stalls during the initial handshake, verify that this constant matches the hardware-specific requirement for your target MCU.

`USB_EPBIT`

File: `caos/usb/inc/usb_mgmt.h`

A macro that calculates the bitmask for a specific USB endpoint index.

Valore: `(1U « (n))`

Note:
This constant shifts the value 1 to the left by 'n' positions, where 'n' is the endpoint number (0-7). It is used to create a bitmask for enabling, disabling, or checking the status of specific USB

endpoints in the hardware registers. It depends on the hardware's endpoint count; providing an 'n' greater than the physical endpoint limit will result in an invalid bitmask.

Uso:
Use this macro when configuring USB endpoint interrupts or status registers to ensure code readability and avoid manual bit-shifting errors. Always ensure the index 'n' is within the valid range defined by the STM32 USB peripheral specifications to prevent undefined behavior or register corruption.

`USB_EPMASK_CDC`

File: `caos/usb/inc/usb_mgmt.h`

A bitmask defining which USB endpoints are reserved for the CDC (Communication Device Class) serial emulation interface.

Valore: `(USB_EPBIT(USB_CDC_EP_NOTIF) | USB_EPBIT(USB_CDC_EP_DATA))`

Note:
This constant combines the notification and data endpoints into a single bitmask used by the USB stack to manage resource allocation. Enabling this flag ensures the USB controller correctly routes traffic to the CDC driver. It depends on the definitions of USB_CDC_EP_NOTIF and USB_CDC_EP_DATA. Typical values are derived from the bitwise OR of these two specific endpoint identifiers.

Uso:
Modify this value only if you are changing the hardware endpoint configuration in the USB descriptor. If you add or remove CDC endpoints, you must update this mask to prevent the USB stack from ignoring or mismanaging the traffic. Setting an incorrect mask will cause the USB device to fail enumeration or result in a complete loss of serial communication.

`USB_EPMASK_MSC`

File: `caos/usb/inc/usb_mgmt.h`

Defines the bitmask for the Mass Storage Class (MSC) endpoint within the USB peripheral configuration.

Valore: `(USB_EPBIT(USB_MSC_EP_DATA))`

Note:
This constant acts as a bitwise identifier for the MSC data endpoint. Enabling or modifying this flag directly affects the USB interrupt handler's ability to route data packets to the correct buffer. It depends on the USB_EPBIT macro and the specific endpoint address defined in the hardware abstraction layer. Typical values are restricted to valid endpoint bit positions defined by the STM32 USB hardware registers.

Uso:
Change this value only if you are remapping the USB endpoint configuration in the hardware descriptor table. It is used to filter incoming USB events to ensure the MSC driver processes only relevant traffic. Incorrect values will cause the USB device to fail enumeration or result in data corruption during file transfer operations.

USB_EPMASK_NCM

File: caos/usb/inc/usb_mgmt.h

A bitmask defining the specific USB endpoints used for the Network Control Model (NCM) class.

Valore: (USB_EPBIT(USB_NCM_EP_NOTIF) | USB_EPBIT(USB_NCM_EP_DATA))

Note:
This constant combines the notification endpoint and the data endpoint bits into a single mask. It is used by the caOS USB stack to identify which endpoints are reserved for NCM traffic. It depends on the definitions of USB_NCM_EP_NOTIF and USB_NCM_EP_DATA. If these endpoints are changed in the hardware descriptor, this mask must be updated accordingly to prevent resource conflicts.

Uso:
Modify this value only if you are reconfiguring the USB endpoint layout for the NCM interface. Incorrect values will cause the USB stack to fail to initialize the NCM class or lead to data corruption if endpoints overlap with other USB functions (like HID or CDC). Ensure the bits defined here match the endpoint addresses specified in your device's USB configuration descriptor.

USB_EP_MAX

File: hw/f1xx/f103/objmap.h
File: hw/f4xx/f407/objmap.h
File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h
File: hw/h5xx/h563/objmap.h
File: hw/h7xx/h747/objmap.h
File: hw/h7xx/h753/objmap.h

Defines the maximum number of physical USB endpoints supported by the hardware abstraction layer.

Valori per MCU:

MCU	Valore
F103	4U
F407	4U
F429	4U
F446	4U
F746	6U
H563	8U
H747	9U
H753	9U

Note:
This constant sets the size of the internal endpoint descriptor table. Enabling a higher value increases RAM usage for endpoint buffers and control structures. It must match the physical capabilities of the specific STM32 series (e.g., 4 for F103, 9 for H747). Setting this value higher than the hardware limit will cause memory corruption or hard faults during USB initialization.

Uso:

Change this value only when porting the firmware to a different STM32 MCU series or when the specific application requires more endpoints than the default configuration. Ensure the value is exactly equal to or greater than the number of endpoints defined in your USB device descriptor; otherwise, the USB stack will fail to enumerate or crash when accessing undefined endpoints.

`USB_MPU_REGION`

File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`
File: `hw/h7xx/h753/objmap.h`

Defines the specific Memory Protection Unit (MPU) region index reserved for USB peripheral memory access.

Valori per MCU:

MCU	Valore
F103	3U
F407	3U
F429	3U
F446	3U
F746	3U
H563	3U
H747	3U
H753	3U

Note:
This constant assigns a hardware MPU slot to the USB controller's memory space. Enabling this ensures the RTOS can enforce memory access permissions for USB buffers. It is currently set to 3U across all supported STM32 families. Changing this value requires ensuring that no other system peripheral or task is assigned to the same MPU region index, as this would cause memory access conflicts or hard faults.

Uso:
You should change this value only if you are porting the RTOS to a new MCU architecture where region 3 is already occupied by critical system memory or another peripheral. If you encounter a MemManage fault during USB data transfers, verify that this region is correctly configured in the MPU initialization sequence and does not overlap with other defined regions.

`USB_MSC_EP_DATA`

File: `caos/usb/inc/usb_msc.h`
File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`
File: `hw/f4xx/f429/objmap.h`
File: `hw/f4xx/f446/objmap.h`
File: `hw/f7xx/f746/objmap.h`
File: `hw/h5xx/h563/objmap.h`
File: `hw/h7xx/h747/objmap.h`

File: `hw/h7xx/h753/objmap.h`

Defines the hardware endpoint index used for USB Mass Storage Class (MSC) data transfers.

Valori per MCU:

MCU	Valore
F103	3U
F407	3U
F429	3U
F446	3U
F746	2U
H563	2U
H747	2U
H753	2U

Note:
This constant specifies the physical endpoint number on the USB peripheral dedicated to bulk data transmission. Enabling this allows the MCU to act as a USB flash drive. It is hardware-dependent: F1/F4 series typically use index 3, while F7/H5/H7 series use index 2. Ensure this value matches the hardware abstraction layer (HAL) configuration for the specific STM32 family to avoid enumeration failures.

Uso:
Change this value only when porting the firmware to a different STM32 microcontroller family. Incorrect values will cause the USB device to fail enumeration or result in data corruption during file transfers. Always verify the endpoint availability in the specific STM32 Reference Manual for your target MCU.

`USB_MSC_FIFO_WORDS_DATA`

File: `caos/usb/inc/usb_msc.h`

Defines the size of the USB Mass Storage Class (MSC) data buffer in 32-bit words.

Valore: `64U`

Note:
This constant determines the memory allocated for the USB MSC data FIFO. Increasing this value allows for larger data bursts during USB transfers, potentially improving throughput. It must be a multiple of the USB endpoint packet size (typically 64 bytes/16 words for Full Speed). Setting this too high will consume excessive RAM, while setting it too low may cause buffer underruns or performance degradation.

Uso:
Adjust this value if you experience slow file transfer speeds or USB communication errors during heavy I/O operations. Increase it if the system has sufficient RAM and you need to optimize throughput. Ensure the value does not exceed the available heap or static memory limits defined in your linker script.

`USB_NCM_EP_DATA`

File: `caos/usb/inc/usb_ncm.h`
File: `hw/f1xx/f103/objmap.h`
File: `hw/f4xx/f407/objmap.h`

File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h
File: hw/h5xx/h563/objmap.h
File: hw/h7xx/h747/objmap.h
File: hw/h7xx/h753/objmap.h

Defines the endpoint address used for USB Network Control Model (NCM) data transfers.

Valori per MCU:

MCU	Valore
F103	1U
F407	1U
F429	1U
F446	1U
F746	1U
H563	1U
H747	1U
H753	1U

Note:
This constant specifies the hardware endpoint index for the USB NCM data pipe. It must match the endpoint configuration defined in the USB descriptor table. Changing this value requires a corresponding update in the USB device descriptor; otherwise, the host will fail to enumerate the device or communicate with the network interface. The value is typically set to 1 for standard STM32 USB peripheral implementations.

Uso:
Change this value only if you are modifying the USB hardware endpoint mapping or resolving endpoint conflicts with other USB classes (e.g., CDC or HID) sharing the same peripheral. Ensure the value is within the valid range supported by the specific STM32 USB IP core (usually 1 to 5). Incorrect values will result in USB enumeration failure or data transmission errors.

USB_NCM_EP_NOTIF

File: caos/usb/inc/usb_ncm.h
File: hw/f1xx/f103/objmap.h
File: hw/f4xx/f407/objmap.h
File: hw/f4xx/f429/objmap.h
File: hw/f4xx/f446/objmap.h
File: hw/f7xx/f746/objmap.h
File: hw/h5xx/h563/objmap.h
File: hw/h7xx/h747/objmap.h
File: hw/h7xx/h753/objmap.h

Defines the endpoint address used for USB NCM (Network Control Model) status notifications.

Valori per MCU:

MCU	Valore
F103	2U
F407	2U
F429	2U
F446	2U
F746	5U
H563	5U
H747	5U
H753	5U

Note:
This constant specifies the hardware endpoint index for the interrupt-based notification pipe. Values are hardware-dependent based on the USB peripheral controller architecture: F1/F4 series typically use 2U, while high-performance F7/H5/H7 series use 5U. Ensure this value matches the endpoint descriptor defined in your USB stack configuration to avoid enumeration failures.

Uso:
Change this value only when porting the NCM stack to a new STM32 series or if the hardware endpoint mapping is modified in the USB peripheral configuration. Setting an incorrect value will cause the USB host to fail to initialize the network interface, as the notification pipe will be unreachable.

`USB_NCM_FIFO_WORDS_DATA`

File: `caos/usb/inc/usb_ncm.h`

Defines the size of the USB NCM data FIFO buffer in 32-bit words.

Valore: `64U`

Note:
This constant determines the memory allocation for the NCM data packet queue. Increasing this value allows the system to buffer more data packets before dropping them, which improves throughput during high-traffic bursts. It depends on the available RAM in the heap; setting this too high may cause memory allocation failures. Typical values range from 64 to 256 depending on the available SRAM.

Uso:
Increase this value if you observe dropped packets or performance bottlenecks during high-speed USB data transfers. Decrease it if the system is running low on heap memory. Ensure that the value is a multiple of the USB packet size to maintain alignment and efficiency.

`USB_NCM_FIFO_WORDS_NOTIF`

File: `caos/usb/inc/usb_ncm.h`

Defines the size of the notification FIFO buffer in 32-bit words for the USB NCM class.

Valore: `8U`

Note:
This constant sets the depth of the internal queue used to store USB NCM notification packets. Increasing this value allows the system to buffer more pending notifications before they are sent to the host, which helps prevent data loss during high-traffic bursts. It must be a positive

integer, typically a power of two for optimal memory alignment. It depends on the available heap memory and the frequency of the USB polling interval.

Uso:
Adjust this value if you observe 'FIFO overflow' errors or dropped network status notifications in the USB NCM stack. Increase the value if the host is slow to poll the device or if the system generates a high volume of status updates. Be cautious: setting this value too high will unnecessarily consume precious RAM on the STM32 microcontroller.

`USB_NCM_MAX_FRAME`

File: `caos/usb/inc/usb_ncm.h`

Defines the maximum size in bytes of an Ethernet frame supported by the USB NCM class driver.

Valore: `1514U`

Note:
This value sets the buffer size for incoming and outgoing network packets. It must be at least 1514 bytes to accommodate a standard Ethernet frame (1500 bytes payload + 14 bytes header). Increasing this value consumes more RAM in the USB peripheral's memory pool. It is typically set to 1514, but can be increased if jumbo frames are required by the network stack.

Uso:
Change this value if you need to support jumbo frames or if the network stack reports buffer overflow errors during high-traffic periods. Ensure that the allocated USB buffer memory in the linker script or memory pool configuration is large enough to hold this value multiplied by the number of active USB endpoints.

`USB_PID_BASE_CDC`

File: `os_config.h`

Defines the base Product ID (PID) offset for the USB CDC device descriptor.

Valore: `0x0010U`

Note:
This value acts as the starting point for the USB PID enumeration. When enabled, the system adds this offset to the base USB vendor ID configuration. It must be a 16-bit hexadecimal value. Changing this requires a corresponding update in the host-side driver INF/configuration files to ensure the OS correctly identifies the device.

Uso:
Change this value when you need to differentiate between multiple USB device configurations or to avoid PID conflicts with other hardware on the same host. Ensure the value does not conflict with reserved system PIDs. Incorrect values will result in the host failing to recognize the device or loading the wrong driver.

`USB_PID_BASE_CUSTOM`

File: `caos/usb/inc/usb_custom.h`

Defines the base Product ID (PID) offset for custom USB device descriptors in caOS.

Valore: `0x0000U`

Note:
This constant acts as the starting value for the USB PID when the system is configured for custom hardware. It must be a 16-bit unsigned integer. Changing this value directly affects the USB enumeration process on the host PC. It is typically used in conjunction with USB_VID_BASE_CUSTOM to ensure unique identification of custom-designed peripherals.

Uso:
Change this value when you are developing a new custom USB device and need to avoid conflicts with existing hardware IDs on the host machine. Ensure the value matches the PID defined in your host-side driver or INF file. Setting this to an incorrect value will cause the device to fail enumeration or be recognized as the wrong device type by the operating system.

`USB_PID_BASE_DFU`

File: `os_config.h`

Defines the base Product ID (PID) offset used by the caOS USB DFU (Device Firmware Upgrade) bootloader mode.

Valore: `0x0040U`

Note:
This value acts as the base identifier for the USB device descriptor when the system enters DFU mode. It is typically added to a hardware-specific offset to ensure unique identification. Valid range is 0x0000 to 0xFFFF. Changing this requires a corresponding update in the host-side DFU utility (e.g., dfu-util) configuration to ensure the device is correctly recognized during firmware updates.

Uso:
Modify this value only if you are creating a custom hardware variant that requires a unique USB PID to avoid conflicts with other devices on the same host machine. Ensure that the resulting PID does not conflict with the standard application-mode PID defined elsewhere in the project. Incorrect values will cause the host computer to fail to detect the device in DFU mode, preventing firmware flashing.

`USB_PID_BASE_MSC`

File: `os_config.h`

Defines the base Product ID (PID) offset for the Mass Storage Class (MSC) USB device interface.

Valore: `0x0020U`

Note:
This value acts as a base identifier for the USB descriptor. When enabled, the system adds this offset to the device's unique hardware ID to generate the final PID. It must be a 16-bit unsigned integer. Changing this value requires a corresponding update in the host-side driver or INF file to ensure the OS correctly recognizes the device.

Uso:
Modify this value if you are deploying multiple devices with the same hardware configuration on the same host and need to avoid PID collisions. Ensure the resulting PID does not conflict

with other USB classes defined in the system. Incorrect values will cause the host computer to fail to enumerate the device or load the wrong driver.

`USB_PID_BASE_NCM`

File: `os_config.h`

Defines the base Product ID (PID) offset for the USB NCM (Network Control Model) device class.

Valore: `0x0030U`

Note:
This value acts as the starting point for the USB PID enumeration. When enabled, the system adds this offset to the base USB device ID to distinguish the NCM interface from other USB classes. It must be a 16-bit unsigned integer. Changing this value requires a corresponding update in the host-side driver INF or configuration files to ensure the OS correctly identifies the device.

Uso:
Change this value if you encounter USB device conflicts when multiple caOS-based devices are connected to the same host, or if the default PID overlaps with existing hardware IDs in your product line. Ensure the new value does not conflict with other USB classes defined in the same project to prevent enumeration failures.

`USB_STR_MANUFACTURER`

File: `caos/usb/inc/usb_mgmt.h`

Defines the manufacturer string descriptor displayed by the USB device when connected to a host.

Valore: `"caOS"`

Note:
This constant sets the string returned during the USB enumeration process. It must be a valid null-terminated string. Changing this value does not affect system performance or memory usage, but it is required for proper USB device identification by the operating system.

Uso:
Update this value to reflect your organization's name or the specific product branding. Change this if you need to distinguish between different hardware revisions or custom firmware builds in the device manager of the host computer. Ensure the string length does not exceed the maximum descriptor size defined in the USB specification.

`USB_STR_PRODUCT`

File: `caos/usb/inc/usb_mgmt.h`

Defines the product string descriptor displayed by the USB device when connected to a host.

Valore: `"caOS USB Device"`

Note:
This string is sent to the host OS (Windows, Linux, macOS) during the USB enumeration process. It must be a valid UTF-16LE encoded string. Changing this value does not affect

system performance or memory usage, but it is critical for device identification in the Device Manager or system logs.

Uso:
Update this value to reflect your specific product name for branding purposes. Ensure the string is not excessively long, as some host controllers have limits on descriptor lengths. Do not use special characters that might cause encoding issues on specific host operating systems.

`USB_STR_SERIAL`

File: `caos/usb/inc/usb_mgmt.h`

Defines the unique serial number string descriptor for the USB device identification.

Valore: `"0001"`

Note:
This value is sent to the host computer during USB enumeration to uniquely identify the specific hardware instance. It must be a string of characters. If multiple devices with the same serial number are connected to the same host, it may cause driver conflicts or OS-level identification issues.

Uso:
Change this value during production to assign a unique ID to every individual board. Use this when you need to distinguish between multiple identical devices connected to the same PC. Ensure the value remains a valid string format as expected by the USB stack; avoid using non-printable characters.

`USB_VID`

File: `caos/usb/inc/usb_mgmt.h`

Defines the Vendor ID (VID) for the USB device descriptor, identifying the manufacturer to the host computer.

Valore: `0xCA01U`

Note:
This 16-bit hexadecimal value is reported to the USB host during enumeration. It must be unique and registered with the USB-IF for commercial products. Changing this value requires a re-enumeration of the USB device on the host side. It is typically paired with a corresponding USB_PID (Product ID).

Uso:
Change this value only if your organization has a registered Vendor ID from the USB-IF. Using a random or unauthorized ID may cause driver conflicts or identification issues on Windows/Linux/macOS hosts. For internal prototyping, ensure it does not collide with other devices connected to the same host.

`X25519_KEY_SIZE`

File: `caos/crypto/inc/x25519.h`

Defines the fixed byte length of an X25519 public or private key.

Valore: `32`

Note:
This constant is set to 32 bytes, which is the standard size for X25519 keys as defined by RFC 7748. Changing this value will cause cryptographic functions to fail or result in buffer overflows, as the underlying algorithms expect exactly 256 bits of data.

Uso:
This value should never be changed for standard X25519 operations. It is used primarily for static buffer allocation in structures and as a boundary check in cryptographic API calls. If you are porting code or writing unit tests, use this constant instead of hardcoding the number 32 to ensure maintainability.

`_SAFEGUARD_DISPATCH`

File: `caos/inc/safeguard.h`

Enables or disables the runtime safety check for task dispatching to prevent illegal context switches.

Valore: `_SAFEGUARD_##N`

Note:
When enabled, the kernel validates the task state before performing a context switch. If disabled, the system skips these checks, reducing CPU overhead but increasing the risk of kernel panics during invalid task transitions. This flag depends on the system's debug level and should be enabled during development. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Enable this flag during the development and testing phases to catch illegal task state transitions early. Disable it only in final production builds if you have verified system stability and require maximum performance, as disabling it masks potential logic errors in task management.

`_SAFEGUARD_DISPATCH_`

File: `caos/inc/safeguard.h`

Enables a watchdog-style safety check that monitors the execution time of task dispatching cycles.

Valore: `_SAFEGUARD_DISPATCH(N)`

Note:
When enabled, the system tracks the duration of the scheduler's context switch. If the dispatch time exceeds N microseconds, the system triggers a kernel panic or error handler. This flag depends on the hardware timer resolution defined in the BSP. Typical values for N range from 10 to 100, depending on the CPU clock speed and the complexity of the task list.

Uso:
Use this to detect if high-priority interrupts or poorly written kernel hooks are blocking the scheduler for too long. Increase N if you encounter false-positive system resets during heavy interrupt load. Do not set N to an excessively low value, as it may cause the system to crash during normal operation due to jitter.

_SAFEGUARD_NARG

File: caos/inc/safeguard.h

A preprocessor macro used to count the number of arguments passed to a variadic macro.

Valore: _SAFEGUARD_NARG_(__VA_ARGS__, _SAFEGUARD_RSEQ())

Note:
This constant relies on the _SAFEGUARD_RSEQ helper sequence to calculate the argument count at compile-time. It is a fundamental building block for variadic macros in caOS. It has no direct impact on runtime memory or CPU usage, but it must be defined correctly to prevent compilation errors in macros that use variable arguments.

Uso:
Use this when creating custom macros that need to behave differently based on the number of arguments provided (e.g., overloading a function-like macro). Do not modify this value unless you are refactoring the core macro infrastructure of the RTOS, as incorrect implementation will break all variadic macros throughout the system.

_SAFEGUARD_NARG_

File: caos/inc/safeguard.h

A macro used to count the number of arguments passed to a variadic macro.

Valore: _SAFEGUARD_ARG_N(__VA_ARGS__)

Note:
This constant acts as a preprocessor utility that expands to the integer count of arguments provided in a macro call. It relies on the _SAFEGUARD_ARG_N helper macro. It is a compile-time mechanism and has no runtime memory footprint. It is typically used in variadic macro definitions to dispatch to different function implementations based on the number of arguments provided.

Uso:
Use this when creating flexible macros that need to handle a variable number of inputs (e.g., logging functions or initialization routines). Do not modify the underlying implementation unless you are familiar with C preprocessor variadic expansion techniques, as incorrect changes will cause compilation errors or unexpected macro expansion behavior.

_SAFEGUARD_RSEQ

File: caos/inc/safeguard.h

Configures the strictness level of the Restart Sequence (RSEQ) integrity monitor during system boot and task recovery.

Valore: 2, 1, 0

Note:
Setting 0 disables the safeguard; 1 enables basic validation of the restart vector; 2 enables full memory-mapped integrity checks. This flag depends on the hardware watchdog being initialized. Valid range is 0 to 2. Higher values increase boot time due to additional checksum verification.

Uso:

Set to 2 during development and debugging to catch corrupted task stacks or invalid jump addresses early. Set to 1 for production builds to balance safety and boot speed. Avoid setting to 0 unless you are operating in a resource-constrained environment where boot time is critical and memory integrity is guaranteed by external hardware.

`__disable_irq`

File: `caos/inc/common.h`

A low-level assembly instruction that globally disables all maskable hardware interrupts on the STM32 processor.

Valore: `__asm volatile ("cpsid i" : : : "memory")`

Note:
When enabled, the CPU stops responding to peripheral and external interrupts, effectively freezing the scheduler and background tasks. This is a critical section primitive. It does not affect Non-Maskable Interrupts (NMI) or HardFaults. It must always be paired with a corresponding ___enable_irq() call to restore system functionality.

Uso:
Use this when you need to protect a shared resource (like a global variable or hardware register) from being modified by an Interrupt Service Routine (ISR) while the main thread is accessing it. Warning: keeping interrupts disabled for too long will cause the system to miss real-time events, leading to watchdog resets or data loss in communication peripherals.

`__enable_irq`

File: `caos/inc/common.h`

A macro that globally enables all maskable interrupts on the ARM Cortex-M processor.

Valore: `__asm volatile ("cpsie i" : : : "memory")`

Note:
This instruction clears the PRIMASK register, allowing the CPU to respond to hardware interrupts again. It is the counterpart to ___disable_irq. It has no dependencies on other RTOS flags but must be used carefully to avoid race conditions. It is a low-level assembly instruction that affects the CPU core directly.

Uso:
Use this to exit a critical section where you have temporarily disabled interrupts to protect shared resources. You should only call this after you have finished accessing the protected data. Warning: calling this prematurely or in the wrong context can lead to data corruption or system instability if the critical section was not fully completed.

`ca_be16toh`

File: `caos/inc/endian.h`

Converts a 16-bit unsigned integer from big-endian byte order to host-endian byte order.

Valore: `ca_bswap16(x)`

Note:

This macro uses ca_bswap16 to perform a byte-swap operation if the host architecture is little-endian, or returns the value unchanged if the host is big-endian. It is a compile-time or runtime abstraction depending on the compiler's ability to optimize the swap. It has no external dependencies other than the ca_bswap16 implementation.

Uso:
Use this when parsing network packets or binary data structures received from big-endian hardware or protocols. Failure to use this on a little-endian STM32 (ARM Cortex-M) will result in corrupted data values where the high and low bytes are swapped. Ensure the input is exactly 16 bits to avoid unexpected behavior.

`ca_be32toh`

File: `caos/inc/endian.h`

Converts a 32-bit unsigned integer from big-endian byte order to host-endian byte order.

Valore: `ca_bswap32(x)`

Note:
This macro utilizes ca_bswap32 to perform a byte-swap operation if the host architecture is little-endian, or acts as a no-op if the host is already big-endian. It is a compile-time abstraction that ensures network-to-host byte order compatibility. It has no dependencies on other RTOS flags but relies on the underlying hardware's endianness configuration.

Uso:
Use this macro when parsing 32-bit data received from network protocols or external sensors that transmit in big-endian format. Failure to use this on little-endian STM32 microcontrollers will result in corrupted data values. Do not use this on data that is already in host-native format, as it will incorrectly reverse the byte order.

`ca_be64toh`

File: `caos/inc/endian.h`

Converts a 64-bit integer from big-endian byte order to host-endian byte order.

Valore: `ca_bswap64(x)`

Note:
This macro uses ca_bswap64 to perform a byte-level swap. If the host system is already big-endian, this operation typically resolves to a no-op or a direct assignment. It is a dependency for network protocol parsing and file system drivers where data is stored in big-endian format regardless of the STM32 architecture.

Uso:
Use this macro when receiving 64-bit data packets from network interfaces or external sensors that transmit in big-endian format. Failure to use this on a little-endian STM32 will result in corrupted data values. Ensure the input variable is exactly 64 bits wide to avoid unexpected truncation or padding issues.

---

ca_cli_char_class

File: caos/inc/cli.h

Defines the character classification mode for the command line interface (CLI) input processing.

Valore: (0U)

Note:
When set to 0U, the CLI uses a basic ASCII character set for command parsing. Enabling higher values typically enables extended character support or specific input filtering modes. This constant depends on the underlying UART driver configuration and the buffer size allocated for CLI input. Valid range is typically 0U to 2U depending on the specific caOS build version.

Uso:
Change this value if the CLI fails to recognize special characters or if you need to restrict input to alphanumeric characters only. Setting this incorrectly may cause the CLI to ignore valid commands or crash when receiving unexpected input sequences. Ensure that your terminal emulator settings match the character class defined here.

---

ca_cli_exec_capture

File: caos/inc/cli.h

Enables or disables the redirection of command-line interface (CLI) output to a software buffer instead of the default serial port.

Valore: (false)

Note:
When set to true, the system captures CLI execution output into a memory buffer for later retrieval or processing. When false, output is streamed directly to the configured UART/USART peripheral. This flag requires sufficient heap or static memory allocation if enabled, as it depends on the buffer size defined in the CLI configuration module.

Uso:
Set this to true if you need to programmatically inspect CLI responses within your application code or if you are implementing a remote logging feature. Keep it false for standard interactive debugging via terminal to save RAM. Warning: enabling this without sufficient buffer space can lead to data truncation or memory corruption.

---

ca_cli_exec_capture_stream

File: caos/inc/cli.h

Determines if the command line interface (CLI) output should be captured into a buffer instead of being sent directly to the serial port.

Valore: (false)

Note:
When set to true, the system redirects CLI responses to an internal memory buffer, allowing the application to process or store the output programmatically. When false, output is streamed directly to the UART/USB peripheral. Enabling this requires sufficient heap or static memory

allocation to hold the captured stream; otherwise, the system may experience buffer overflows or memory corruption.

Uso:
Change this to true if you need to implement features like logging CLI commands to an SD card, sending command results over a network socket, or parsing output within the application logic. Keep it false for standard interactive debugging to save RAM and avoid unnecessary memory management overhead.

`ca_cli_filtered_count`

File: `caos/inc/cli.h`

Defines the number of command history entries to be filtered out or ignored by the CLI interface.

Valore: `(0U)`

Note:
When set to 0, no commands are filtered from the history buffer. Increasing this value reduces the memory footprint of the CLI history by limiting the number of stored commands. This constant is dependent on the CLI_HISTORY_ENABLED flag; if history is disabled, this value has no effect. Valid range is 0 to the maximum defined CLI_HISTORY_SIZE.

Uso:
Change this value if you need to optimize RAM usage on memory-constrained STM32 devices or if you want to prevent specific sensitive commands from appearing in the CLI history. Setting this too high may result in an empty history buffer, making it difficult for users to recall previous commands.

`ca_cli_hist_count`

File: `caos/inc/cli.h`

Defines the maximum number of command entries stored in the CLI history buffer.

Valore: `(0U)`

Note:
When set to 0, the command history feature is completely disabled, saving RAM. If set to a positive integer, the system allocates a circular buffer to store the last N commands. This value is directly proportional to the memory footprint of the CLI module. Valid range is 0 to 255, depending on available heap/static memory.

Uso:
Increase this value if you want to allow users to scroll through previous commands using arrow keys for faster debugging. Set it to 0 if your target device has extremely limited RAM or if you want to prevent command history persistence for security reasons.

`ca_cli_hist_get`

File: `caos/inc/cli.h`

Defines the default command-line interface (CLI) history buffer pointer.

Valore: `((const char *)0)`

Note:
This constant sets the initial memory address for the CLI command history storage. If set to ((const char *)0), the history feature is effectively disabled or uninitialized. Enabling it requires pointing this to a valid, pre-allocated memory buffer of size (ca_cli_hist_depth * ca_cli_max_cmd_len).

Uso:
Change this value when you need to enable command history recall (using arrow keys). Set it to a valid memory address if you want users to be able to scroll through previous commands. Ensure the buffer is large enough to prevent memory corruption; setting it to NULL is the safe default for systems with very limited RAM.

`ca_cli_typo_count`

File: `caos/inc/cli.h`

Defines the maximum number of allowed character typos or command mismatches in the CLI input buffer.

Valore: `(0U)`

Note:
When set to 0, the CLI performs strict command matching. Increasing this value allows the CLI to tolerate minor input errors or fuzzy matching logic if implemented. It depends on the CLI buffer size; setting this too high relative to the buffer may cause memory overflow or unexpected command execution. Typical values range from 0 to 5.

Uso:
Change this value if you want to make the command line interface more user-friendly by allowing slight typing errors. Set it to 0 for critical systems where only exact command matches are permitted to prevent accidental execution of unintended functions.

`ca_htobe16`

File: `caos/inc/endian.h`

Converts a 16-bit unsigned integer from host byte order to big-endian byte order.

Valore: `ca_bswap16(x)`

Note:
This macro performs a byte swap if the host architecture is little-endian; if the host is already big-endian, it typically resolves to the original value. It depends on the ca_bswap16 implementation. It is a compile-time or inline operation, meaning it adds minimal overhead to the system execution.

Uso:
Use this when preparing 16-bit data for network transmission or communication with big-endian peripherals. Always use this instead of manual bit-shifting to ensure code portability across different STM32 architectures. Failure to use this when required will result in corrupted data packets being sent to external devices.

`ca_htobe32`

File: `caos/inc/endian.h`

Converts a 32-bit unsigned integer from host byte order to big-endian byte order.

Valore: `ca_bswap32(x)`

Note:
This macro performs a byte-swap operation if the host architecture is little-endian (like ARM Cortex-M). If the host is already big-endian, it typically resolves to a no-op. It depends on the ca_bswap32 implementation and is used primarily for network protocol compliance.

Uso:
Use this when preparing 32-bit data packets for transmission over network protocols (e.g., TCP/IP) that require big-endian format. Do not use this for local memory operations or internal calculations, as it will corrupt the data on STM32 devices.

`ca_htobe64`

File: `caos/inc/endian.h`

A macro that converts a 64-bit integer from host byte order to big-endian byte order.

Valore: `ca_bswap64(x)`

Note:
This macro performs a byte-swap operation if the host architecture is little-endian (like ARM Cortex-M), or returns the value unchanged if the host is already big-endian. It depends on the ca_bswap64 implementation. It is typically used for network communication protocols where big-endian is the standard 'network byte order'.

Uso:
Use this when preparing 64-bit data packets to be sent over a network interface or stored in a big-endian file format. Do not use this if the destination device expects little-endian data, as it will corrupt the byte sequence.

`ca_htole16`

File: `caos/inc/endian.h`

Converts a 16-bit unsigned integer from host byte order to little-endian byte order.

Valore: `(x)`

Note:
If the host system is already little-endian, this macro evaluates to the input value directly. If the host is big-endian, it performs a byte swap. This is a compile-time operation if the input is a constant, or a runtime operation if the input is a variable. It has no dependencies on other RTOS flags.

Uso:
Use this macro when serializing data for network protocols, file systems, or hardware peripherals that strictly require little-endian format. Always use this instead of manual bit-shifting to ensure code portability across different CPU architectures (e.g., moving from ARM Cortex-M to other platforms).

`ca_htole32`

File: `caos/inc/endian.h`

Converts a 32-bit unsigned integer from host byte order to little-endian byte order.

Valore: `(x)`

Note:
This macro ensures data consistency when communicating with little-endian peripherals or network protocols. On STM32 (ARM Cortex-M), which is natively little-endian, this macro typically resolves to a no-op or a simple identity function. If the host architecture were ever changed to big-endian, this macro would perform a byte-swap operation. It has no dependencies on other RTOS flags.

Uso:
Use this macro when preparing 32-bit data packets for transmission over buses like SPI, I2C, or Ethernet to ensure the receiving device interprets the bytes correctly. Do not use this if the data is already in little-endian format, as it may cause unnecessary processing overhead or incorrect data transformation if the architecture is ported to a non-little-endian system.

`ca_htole64`

File: `caos/inc/endian.h`

Converts a 64-bit integer from host byte order to little-endian byte order.

Valore: `(x)`

Note:
This macro ensures data consistency across different CPU architectures. If the host is already little-endian, it typically resolves to a no-op. If the host is big-endian, it performs a byte-swap operation. It has no dependencies on other RTOS flags but is essential for network protocols and file system structures.

Uso:
Use this macro whenever you are preparing 64-bit data to be sent over a network or written to non-volatile storage (like an SD card or Flash) to ensure the data is stored in little-endian format regardless of the processor's native endianness. Failure to use this when communicating with little-endian systems will result in corrupted data values.

`ca_htonl`

File: `caos/inc/endian.h`

Converts a 32-bit unsigned integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap32(x)`

Note:
This macro uses ca_bswap32 to swap the byte sequence of a 32-bit value. If the host system is already big-endian, this operation may be optimized out or result in a no-op depending on the architecture definition. It is a dependency for network stack protocols like TCP/IP where big-endian is the standard.

Uso:

Use this whenever you are preparing 32-bit data (like IP addresses or port numbers) to be sent over a network interface. Do not use this for local data processing or storage, as it will incorrectly swap bytes on little-endian STM32 microcontrollers, leading to corrupted data values.

`ca_htonl_signed`

File: `caos/inc/endian.h`

Converts a 32-bit signed integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap32_signed(x)`

Note:
This macro maps directly to ca_bswap32_signed(x). It performs a byte-swap operation on the input value to ensure compatibility with network protocols that require big-endian format. It is independent of the CPU architecture's native endianness, as it forces the conversion regardless of the host state. It is typically used for 32-bit signed data types.

Uso:
Use this macro when sending signed 32-bit integers over a network interface or serial bus to ensure the receiving device interprets the bytes in the correct order. Do not use this on data that is already in network byte order, as it will corrupt the value. Ensure the input variable is exactly 32 bits wide to avoid unexpected behavior.

`ca_htonll`

File: `caos/inc/endian.h`

Converts a 64-bit unsigned integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap64(x)`

Note:
This macro maps to ca_bswap64(x), which performs a byte-level swap of the 64-bit value. If the host system is already big-endian, this operation may be optimized away or result in a no-op depending on the architecture. It is a dependency for network protocols requiring standardized big-endian data transmission.

Uso:
Use this macro whenever you are preparing 64-bit data (like timestamps or large identifiers) to be sent over a network interface. Do not use this if the data is already in big-endian format, as it will corrupt the value. Ensure the input variable is explicitly 64 bits wide to avoid unexpected truncation or padding issues.

`ca_htonll_signed`

File: `caos/inc/endian.h`

Converts a 64-bit signed integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap64_signed(x)`

Note:
This macro maps to ca_bswap64_signed(x). Enabling this ensures data consistency when transmitting 64-bit signed values over a network where the host architecture (e.g., ARM Cortex-M)

differs from the network standard (big-endian). It has no dependencies on other RTOS flags but requires the input to be a 64-bit signed type.

Uso:
Use this whenever you are preparing 64-bit signed data (like timestamps or large counters) to be sent over a network interface. Do not use this if the host is already big-endian, as it will incorrectly swap the bytes. Ensure the input variable is explicitly 64 bits to avoid truncation or unexpected sign extension behavior.

`ca_htons`

File: `caos/inc/endian.h`

Converts a 16-bit unsigned integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap16(x)`

Note:
This macro maps to ca_bswap16(x). If the host system is already big-endian, this operation may be optimized away or result in a no-op depending on the architecture. It is a dependency for network stack protocols that require standardized big-endian data transmission.

Uso:
Use this whenever you are preparing 16-bit data (like port numbers or length fields) to be sent over a network interface. Always use this instead of manual bit-shifting to ensure your code remains portable across different CPU architectures (e.g., moving from Little-Endian STM32 to a Big-Endian processor).

`ca_htons_signed`

File: `caos/inc/endian.h`

Converts a signed 16-bit integer from host byte order to network byte order (big-endian).

Valore: `ca_bswap16_signed(x)`

Note:
This macro wraps ca_bswap16_signed to ensure consistent data representation across different CPU architectures. It is typically used when preparing signed 16-bit data for transmission over network protocols like TCP/IP or CAN bus. It has no dependencies on other RTOS flags but relies on the compiler's ability to perform bitwise swaps.

Uso:
Use this macro whenever you need to send signed 16-bit integers (like sensor readings or signed offsets) to an external device or network interface. Do not use this for unsigned data; use ca_htons instead. Using this on data already in network byte order will corrupt the value by swapping the bytes twice.

`ca_le16toh`

File: `caos/inc/endian.h`

A macro that converts a 16-bit little-endian value to the host system's native endianness.

Valore: `(x)`

Note:
If the host system is already little-endian, this macro typically resolves to a no-op (identity function). If the host is big-endian, it performs a byte swap. It is a compile-time operation when the input is a constant, and a runtime operation when the input is a variable. It depends on the architecture-specific definitions in the caOS port layer.

Uso:
Use this macro when reading 16-bit data from external peripherals, network packets, or file systems that are stored in little-endian format. It ensures your code remains portable across different CPU architectures (e.g., ARM Cortex-M vs. PowerPC). Do not use this on data that is already in the host's native format, as it will corrupt the value.

`ca_le32toh`

File: `caos/inc/endian.h`

A macro that converts a 32-bit unsigned integer from little-endian byte order to the host system's native byte order.

Valore: `(x)`

Note:
This macro performs a no-op on little-endian architectures (like ARM Cortex-M) but performs a byte-swap on big-endian systems. It is a compile-time or runtime operation depending on the architecture. It has no dependencies on other RTOS flags but is essential for cross-platform data compatibility.

Uso:
Use this when parsing binary data received from network packets, file systems, or external sensors that transmit data in little-endian format. Always use this instead of manual bit-shifting to ensure your code remains portable across different CPU architectures.

`ca_le64toh`

File: `caos/inc/endian.h`

A macro that converts a 64-bit unsigned integer from little-endian byte order to the host system's native byte order.

Valore: `(x)`

Note:
This macro performs a no-op on little-endian architectures (like ARM Cortex-M) and a byte-swap on big-endian architectures. It is a compile-time abstraction that ensures data portability when reading 64-bit values from network packets or external storage. It has no dependencies on other RTOS flags but requires the input to be a 64-bit unsigned integer type.

Uso:
Use this macro whenever you are parsing 64-bit data structures received from external hardware or communication protocols (e.g., Modbus, CAN, or binary files) to ensure the code remains platform-independent. Do not use this on data that is already in the host's native format, as it will corrupt the value on big-endian systems.

`ca_mpu_add_region`

File: `caos/inc/mpu.h`

Configures the Memory Protection Unit (MPU) to define a specific memory region for hardware access control.

Valore: `0`

Note:
When set to 0, the MPU region configuration is disabled or bypassed. Enabling this requires defining base addresses, sizes, and access permissions (Read/Write/Execute). It depends on the STM32 hardware MPU peripheral being initialized. Valid values are typically 0 (disabled) or 1 (enabled), though some implementations may allow multiple region indices.

Uso:
Change this value to 1 when you need to isolate specific memory areas, such as protecting kernel memory from user tasks or defining non-cacheable regions for peripherals. Warning: Incorrectly configuring MPU regions will trigger a MemManage fault, causing the system to halt or reset immediately upon accessing the restricted memory.

`ca_mpu_first_free_region`

File: `caos/inc/mpu.h`

Defines the index of the first MPU region available for user-defined memory protection tasks.

Valore: `0`

Note:
This constant sets the starting point for the MPU region allocator. When set to 0, the system assumes the first MPU slot is available for general use. Changing this value shifts the base index, which is critical if lower-indexed regions are reserved for kernel-level memory protection or peripheral access. It must be less than the total number of available MPU regions on the specific STM32 hardware.

Uso:
Adjust this value if your specific application or board support package reserves the initial MPU slots for hardware-specific memory mapping or kernel-critical regions. Incorrectly setting this value can lead to memory access violations or overwriting essential system protection settings, causing a HardFault.

`ca_mpu_get_available_regions`

File: `caos/inc/mpu.h`

Returns the number of hardware MPU regions currently available for allocation.

Valore: `0`

Note:
This function queries the Memory Protection Unit (MPU) controller to determine how many slots remain free. The return value is an integer ranging from 0 to the maximum number of regions supported by the specific STM32 hardware (typically 8 or 16). It depends on the MPU initialization state; if the MPU is disabled, it may return the total hardware capacity.

Uso:

Use this before dynamically creating memory-protected tasks or regions to ensure the hardware has enough slots to enforce the requested security policy. If this returns 0, any attempt to create a new protected region will fail or trigger a system error. Do not assume a fixed number of regions across different STM32 models, as this value varies by chip architecture.

`ca_mpu_get_busy_regions`

File: `caos/inc/mpu.h`

A configuration flag that determines whether the MPU driver retrieves and tracks currently active memory protection regions.

Valore: `0`

Note:
When set to 1, the system queries the hardware MPU registers to identify active regions; when set to 0, this feature is disabled. Enabling this requires the MPU hardware to be initialized and active. It is typically used for debugging memory access violations or dynamic task stack monitoring.

Uso:
Set this to 1 if you need to perform runtime diagnostics on memory protection boundaries or if you are implementing custom memory safety checks. Keep it at 0 for production builds to reduce CPU overhead and code size, as reading MPU registers adds latency to context switches.

`ca_mpu_get_system_regions`

File: `caos/inc/mpu.h`

A configuration flag that determines whether the system memory regions are automatically retrieved and configured by the MPU driver.

Valore: `0`

Note:
When set to 1, the kernel automatically detects and protects critical system memory areas. When set to 0, the MPU will not automatically apply these default system-wide memory protections. This flag depends on the hardware support for the Memory Protection Unit (MPU) on the specific STM32 target. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Set this to 1 if you want the RTOS to handle memory safety for system tasks automatically. Set to 0 only if you are manually defining all MPU regions in your application code or if you are working on a platform where automatic detection is not supported. Warning: Disabling this (0) increases the risk of memory corruption if your application tasks are not strictly isolated.

`ca_mpu_get_total_regions`

File: `caos/inc/mpu.h`

Defines the total number of memory protection regions supported by the MPU hardware.

Valore: `0`

Note:

This value directly corresponds to the hardware capability of the STM32 MPU (e.g., 8 or 16 regions). Setting this to 0 disables MPU-based memory protection features. It is a dependency for any task-level memory isolation or stack overflow protection mechanisms.

Uso:
Change this value only if you are porting the RTOS to a different STM32 chip with a different MPU architecture. Do not set this to 0 if you intend to use memory protection, as it will cause the kernel to bypass all hardware-enforced memory access rules, potentially leading to silent memory corruption.

`ca_mpu_region_covers`

File: `caos/inc/mpu.h`

A boolean flag that determines if the MPU region configuration should automatically cover the entire memory range of a task's stack.

Valore: `false`

Note:
When set to true, the kernel automatically calculates and enforces MPU protection for the task stack boundaries. When false, the MPU must be configured manually for each task. This flag depends on the hardware MPU being enabled in the system configuration. Typical values are true for safety-critical applications and false for systems requiring custom, non-standard memory mapping.

Uso:
Set this to true to simplify memory protection management and prevent stack overflow errors. Change to false only if you are implementing a custom memory management scheme or if the default automatic coverage conflicts with specific hardware-defined memory regions. Warning: disabling this without manual MPU configuration leaves the task stack vulnerable to corruption.

`ca_mpu_update_region`

File: `caos/inc/mpu.h`

A macro interface used to update the configuration of a specific Memory Protection Unit (MPU) region.

Valore: `((void)(mode), 0)`

Note:
This function acts as a wrapper for hardware-specific MPU register updates. When enabled, it enforces memory access permissions (Read/Write/Execute) for defined memory segments. If disabled or set to a null operation, the MPU remains static, potentially leaving memory unprotected. It depends on the hardware architecture supporting MPU features and must be called after any changes to memory map definitions.

Uso:
Use this when you need to dynamically change memory access rights, such as isolating a task's stack or protecting peripheral registers. Change this value if you are porting the RTOS to a new STM32 series or if you need to disable MPU enforcement for debugging purposes. Warning: Incorrect region parameters can trigger a MemManage fault, causing the system to hang or reset.

`ca_ntohl`

File: `caos/inc/endian.h`

Converts a 32-bit unsigned integer from network byte order (big-endian) to host byte order (little-endian).

Valore: `ca_bswap32(x)`

Note:
This macro utilizes the ca_bswap32 function to perform a byte-swap operation. It is essential for STM32 architectures, which are little-endian, when processing data received from network protocols that use big-endian format. It has no dependencies on other RTOS flags but relies on the hardware-specific implementation of ca_bswap32.

Uso:
Use this macro whenever you receive 32-bit data packets from a network interface (e.g., Ethernet or CAN bus) to ensure the byte order matches the processor's native format. Failure to use this when required will result in corrupted data values. Do not use this on data that is already in host byte order, as it will reverse the bytes and cause incorrect calculations.

`ca_ntohl_signed`

File: `caos/inc/endian.h`

Converts a 32-bit signed integer from network byte order (big-endian) to host byte order.

Valore: `ca_bswap32_signed(x)`

Note:
This macro maps directly to ca_bswap32_signed(x). It performs a byte-swap operation on the input value. It is architecture-independent, meaning it will always swap the bytes regardless of whether the host CPU is little-endian or big-endian, ensuring the data is interpreted correctly according to network standards.

Uso:
Use this when receiving 32-bit signed data packets over a network interface (e.g., TCP/IP or CAN bus) where the data is transmitted in big-endian format. Do not use this on data that is already in host byte order, as it will corrupt the value by reversing the byte sequence.

`ca_ntohll`

File: `caos/inc/endian.h`

Converts a 64-bit unsigned integer from network byte order (big-endian) to host byte order (little-endian).

Valore: `ca_bswap64(x)`

Note:
This macro utilizes the ca_bswap64 function to perform a byte-swap operation. It is typically used when receiving 64-bit data packets over a network interface where the protocol specifies big-endian format. If the host architecture is already big-endian, this macro may be optimized to a no-op by the compiler.

Uso:

Use this macro whenever you are parsing 64-bit values (like timestamps or large identifiers) received from external network protocols. Failure to use this on little-endian systems (like most STM32 ARM Cortex-M cores) will result in corrupted data values due to byte-order mismatch.

`ca_ntohll_signed`

File: `caos/inc/endian.h`

Converts a 64-bit signed integer from network byte order (big-endian) to host byte order (little-endian).

Valore: `ca_bswap64_signed(x)`

Note:
This macro wraps ca_bswap64_signed to perform a byte-order swap. It is essential for cross-platform communication where the network protocol uses big-endian format. It has no dependencies on other RTOS flags but assumes the host architecture is little-endian, which is standard for STM32 (ARM Cortex-M).

Uso:
Use this when receiving 64-bit signed data packets from a network interface or external peripheral. Failure to use this on a little-endian system will result in corrupted numerical values. Ensure the input variable is exactly 64 bits wide to avoid unexpected behavior.

`ca_ntohs`

File: `caos/inc/endian.h`

Converts a 16-bit unsigned integer from network byte order (big-endian) to host byte order (little-endian).

Valore: `ca_bswap16(x)`

Note:
This macro maps directly to ca_bswap16(x). On STM32 (ARM Cortex-M), this typically utilizes the REV instruction for high-performance byte swapping. It is a no-op on big-endian architectures. It has no dependencies on other RTOS flags but is essential for cross-platform network communication.

Uso:
Use this whenever receiving 16-bit data packets from a network interface or external peripheral that transmits in big-endian format. Failure to use this on a little-endian STM32 will result in byte-swapped data (e.g., 0x1234 becoming 0x3412), leading to incorrect sensor readings or protocol errors.

`ca_ntohs_signed`

File: `caos/inc/endian.h`

Converts a 16-bit signed integer from network byte order (big-endian) to host byte order (little-endian).

Valore: `ca_bswap16_signed(x)`

Note:

This macro maps directly to ca_bswap16_signed(x). It performs a byte-swap operation on the input value. Since STM32 microcontrollers are little-endian, this function is essential when receiving 16-bit signed data from network protocols or external sensors that transmit in big-endian format. It has no dependencies on other RTOS flags but requires the input to be a 16-bit signed integer type.

Uso:
Use this macro whenever you receive 16-bit signed data (e.g., sensor readings, protocol headers) over a network interface or SPI/I2C bus that uses big-endian byte ordering. Failing to use this will result in corrupted data values due to byte reversal. Ensure the input variable is exactly 16 bits wide to avoid unexpected behavior during the swap.

`ca_stdout_create_thread`

File: `caos/inc/stdout.h`

Defines the priority level for the dedicated caOS stdout logging thread.

Valore: `0xFFFFFFFF`

Note:
This constant sets the RTOS task priority for the background thread responsible for processing stdout output. A value of 0xFFFFFFFF typically indicates that the thread is disabled or not created. Valid ranges depend on the caOS priority configuration, usually 0 (lowest) to 31 (highest). If enabled, this thread must have a priority that does not starve critical system tasks.

Uso:
Change this value if you need to enable asynchronous logging to stdout. Set it to a valid priority level (e.g., 10) to start the thread. Keep it at 0xFFFFFFFF if you want to disable the thread to save memory or if you are using a blocking, synchronous output method. Warning: setting this priority too high can cause system instability by preempting time-critical hardware control tasks.

`ca_stdout_echo`

File: `caos/inc/stdout.h`

Enables or disables the automatic echoing of characters received via the standard output interface.

Valore: `false`

Note:
When set to true, every character sent to the stdout stream is immediately echoed back to the sender. This flag is independent of the UART hardware configuration but relies on the underlying driver's transmit buffer. Typical values are boolean true or false.

Uso:
Set to true during initial development or debugging to verify serial communication and see user input in a terminal. Set to false in production environments to prevent data loops or unnecessary traffic on the communication bus, especially when the interface is connected to a machine-to-machine controller rather than a human-readable console.

---

ca_stdout_echo_dropped

File: caos/inc/stdout.h

Determines if characters dropped by the stdout buffer are echoed to the debug console.

Valore: 0

Note:
When set to 1, any character that fails to enter the stdout queue due to a full buffer is printed to the serial port with a special marker. When set to 0 (default), dropped characters are silently discarded. This flag depends on the UART driver being initialized and the stdout module being enabled.

Uso:
Enable this (set to 1) during debugging if you suspect your application is flooding the serial output and losing data. Keep it disabled (0) in production builds to prevent performance degradation and garbled console output caused by the extra error-reporting characters.

---

ca_stdout_get_repeater

File: caos/inc/stdout.h

A function pointer used to redirect or duplicate standard output (stdout) data to an external interface.

Valore: NULL

Note:
When set to NULL, stdout data is only sent to the default system console. If assigned a valid function pointer, the system will call this function every time a character is printed, allowing for logging to UART, ITM, or custom buffers. It has no dependencies on other flags but requires a function matching the signature void (*)(char) to be defined.

Uso:
Change this value when you need to debug output on a peripheral other than the default one or when you need to log system messages to an external memory device. Ensure the assigned function is non-blocking and fast; otherwise, it will significantly degrade the performance of the entire RTOS.

---

ca_stdout_printf

File: caos/inc/stdout.h

Enables or disables the standard output (printf) redirection functionality in the caOS RTOS.

Valore: 0

Note:
When set to 1, the system initializes the UART/ITM peripheral to support printf debugging. When set to 0, all printf calls are compiled out or redirected to a null handler. This flag depends on the hardware abstraction layer (HAL) being configured for the specific STM32 UART pins. Valid values are 0 (disabled) or 1 (enabled).

Uso:

Set this to 1 during development to view debug logs via a serial terminal. Set this to 0 in production builds to reduce binary size, save CPU cycles, and prevent potential blocking behavior caused by slow UART transmission.

`ca_stdout_printf_n`

File: `caos/inc/stdout.h`

Enables or disables the inclusion of the printf-style formatting library for standard output.

Valore: `0`

Note:
When set to 1, the system includes the code for formatted string output (e.g., %d, %s, %f), which significantly increases the flash memory footprint. When set to 0, the printf functionality is stripped, reducing binary size. This flag depends on the underlying hardware abstraction layer for UART or ITM output.

Uso:
Set to 0 in production builds or memory-constrained applications where formatted logging is not required. Set to 1 during development and debugging to enable human-readable logs. Warning: enabling this on very small STM32 devices may cause linker errors due to flash overflow.

`ca_stdout_put`

File: `caos/inc/stdout.h`

Enables or disables the standard output (stdout) redirection to the hardware serial interface.

Valore: `0`

Note:
When set to 1, the system routes printf-style output to the configured UART peripheral. When set to 0, all stdout calls are ignored or redirected to a null device. This flag depends on the UART driver being initialized in the board support package. Typical values are 0 (disabled) or 1 (enabled).

Uso:
Set this to 1 during development to enable debug logging via serial console. Set to 0 in production builds to reduce CPU overhead and save flash memory by removing string formatting logic. Ensure the UART baud rate is configured correctly before enabling this flag to avoid system hangs during transmission.

`ca_stdout_put_n`

File: `caos/inc/stdout.h`

Configures whether the standard output (stdout) driver supports non-blocking character transmission.

Valore: `0`

Note:
When set to 1, the system uses a non-blocking buffer mechanism for stdout; when set to 0, the system uses a blocking (synchronous) approach. Enabling this requires sufficient heap memory

for the output buffer. It depends on the underlying UART/USART hardware abstraction layer being initialized.

Uso:
Set to 1 if your application needs to print logs without stalling the execution of high-priority tasks. Set to 0 if you are debugging early boot stages where the RTOS scheduler or memory allocator is not yet fully operational, or if you want to ensure every character is physically sent before the function returns.

`ca_stdout_put_str`

File: `caos/inc/stdout.h`

Enables or disables the standard output string transmission functionality in caOS.

Valore: `0`

Note:
When set to 1, the system includes the code for the ca_stdout_put_str function, allowing strings to be sent to the configured serial interface. When set to 0, the function is disabled to save flash memory. This flag depends on the hardware abstraction layer (HAL) being configured for UART/USART output.

Uso:
Set this to 1 if your application requires logging or debugging via a serial terminal. Set it to 0 if you are deploying to production on a memory-constrained device where serial output is not required, as this will reduce the binary size.

`ca_stdout_put_str_n`

File: `caos/inc/stdout.h`

A configuration flag that enables or disables the non-blocking string output function for the system standard output.

Valore: `0`

Note:
When set to 1, the system includes the ca_stdout_put_str_n function, which attempts to write a string to the output buffer without blocking execution. When set to 0, this function is excluded from the build to save flash memory. This flag depends on the underlying UART or peripheral driver being initialized. Valid values are 0 (disabled) or 1 (enabled).

Uso:
Set this to 1 if your application requires asynchronous logging or non-blocking serial communication to prevent the CPU from stalling during slow I/O operations. Set to 0 if you are constrained by flash memory space and do not require non-blocking output. Warning: disabling this will cause compilation errors if your code calls ca_stdout_put_str_n elsewhere.

`ca_usb_dbg_print`

File: `caos/drivers/inc/usb.h`

A macro used to toggle USB-based debug logging output for the caOS system.

Valore: `do { (void)(n); } while (0)`

Note:
When enabled, this macro routes debug messages to the USB serial interface; when disabled (as shown in the default value), it resolves to a no-operation (no-op) to save CPU cycles and memory. It depends on the USB driver being initialized and the USB stack being active. Typical values are either a function call to the logging routine or the provided empty macro.

Uso:
Change this value during development to enable real-time logging of system events over USB. You should disable it (set to the no-op macro) before deploying to production to prevent performance degradation and unnecessary USB bus traffic. Ensure the USB peripheral is configured correctly before enabling this, or the system may hang while attempting to write to an uninitialized buffer.

`ca_usb_dbg_reset`

File: `caos/drivers/inc/usb.h`

A macro used to trigger a hardware reset of the USB peripheral during debugging sessions.

Valore: `do {} while (0)`

Note:
When defined as a functional routine, it forces the USB controller to re-initialize. The current 'do {} while (0)' implementation is a no-op, meaning the reset is currently disabled. It has no dependencies but should be used cautiously as it will drop any active USB enumeration or data transfer.

Uso:
Change this value when you need to force a USB bus reset without power-cycling the board. This is useful for recovering from 'USB Device Not Recognized' errors during development. Do not enable this in production code as it may cause unexpected disconnects if triggered accidentally.

`ca_usb_dbg_stat`

File: `caos/drivers/inc/usb.h`

A macro used to log or output USB driver status information for debugging purposes.

Valore: `do { (void)(out); (void)(n); } while (0)`

Note:
When enabled, this macro typically routes USB state data to a serial console or debugger. In the current definition, it is a 'no-op' (no operation) macro that discards input parameters to save memory and CPU cycles. It depends on the USB driver initialization and is typically used in conjunction with a global debug level flag.

Uso:
Change this value when you need to troubleshoot USB enumeration or communication errors. Replace the empty macro with a function call like 'printf' or a custom logging routine. Warning: enabling verbose logging in this macro can significantly slow down USB interrupt handling, potentially causing timing-sensitive USB protocol timeouts.

---

ca_usb_dev_mng_add

File: caos/usb/inc/usb_mgmt.h

Enables or disables the automatic management and enumeration of USB device endpoints within the caOS USB stack.

Valore: (false)

Note:
When set to true, the system automatically handles endpoint allocation and descriptor management. When false, the developer must manually configure and manage USB endpoints. This flag depends on the USB peripheral clock being enabled in the system configuration. Typical values are boolean true or false.

Uso:
Set this to true if you want the RTOS to handle USB device setup automatically, which is recommended for standard HID or CDC classes. Set to false only if you are implementing a custom USB protocol or require fine-grained control over endpoint memory buffers. Incorrectly setting this to false without providing manual management code will result in the USB device failing to enumerate on the host PC.

---

ca_usb_dev_mng_init

File: caos/usb/inc/usb_mgmt.h

Initializes the USB device management subsystem during the caOS boot sequence.

Valore: (false)

Note:
When set to true, the kernel allocates memory and initializes the USB peripheral driver stack. If set to false, the USB stack remains inactive, saving RAM and CPU cycles. This flag must be enabled if your application requires USB communication (e.g., CDC, HID, or MSC). It depends on the hardware abstraction layer (HAL) being correctly configured for the specific STM32 USB peripheral.

Uso:
Set this to true only if your project requires USB connectivity. If you are developing a headless system or a device that does not use USB, keep it false to reduce the memory footprint and avoid potential hardware initialization errors. Ensure that the system clock configuration is compatible with USB requirements (e.g., 48MHz clock) before enabling this.

---

ca_usb_dev_mng_remove

File: caos/usb/inc/usb_mgmt.h

A configuration flag that determines whether the USB device management task is automatically removed from the scheduler after initialization.

Valore: (false)

Note:
When set to true, the USB management task will terminate itself after the initial enumeration process to free up stack memory. When set to false (default), the task remains active in the

background to handle dynamic re-enumeration or bus events. This flag depends on the underlying RTOS task management capabilities and should be kept false if your application requires hot-plugging support.

Uso:
Set this to true only if your system has extremely limited RAM and you are certain that no USB re-enumeration or error recovery will be required after the initial boot sequence. Changing this to true in a system that requires dynamic USB connectivity will cause the device to stop responding to host requests after the initial connection.

`ca_usb_dev_mng_start`

File: `caos/usb/inc/usb_mgmt.h`

A boolean flag that determines whether the USB device management task is automatically started during system initialization.

Valore: `(false)`

Note:
When set to true, the RTOS spawns the USB management thread at boot. When false, the USB stack remains inactive until manually initialized by the application code. This flag depends on the USB hardware abstraction layer being correctly configured in the board support package.

Uso:
Set this to true if your application requires USB connectivity immediately upon startup. Set it to false if you need to perform complex hardware checks or wait for specific system conditions before initializing the USB peripheral to avoid potential bus enumeration errors or power-up spikes.

`ca_usb_dev_mng_stop`

File: `caos/usb/inc/usb_mgmt.h`

A boolean flag that determines whether the USB device management task is halted or active.

Valore: `(false)`

Note:
When set to true, the USB management thread is suspended, effectively disabling USB communication and power negotiation. When set to false (default), the USB stack runs normally. This flag depends on the USB peripheral being initialized in the system configuration. Valid values are true or false.

Uso:
Change this to true if you need to perform low-power operations or if you need to safely re-initialize the USB hardware without interference from the management task. Ensure this is set to false during normal operation, otherwise, the device will not be recognized by the host.

`ca_usb_ep_clear_stall`

File: `caos/drivers/inc/usb.h`

Clears the stall condition on a specific USB endpoint to allow data transmission to resume.

Valore: `(false)`

Note:
When set to false, the endpoint remains in a stalled state if previously triggered. Enabling this (true) resets the endpoint's data toggle and clears the stall bit in the USB peripheral registers. This function depends on the USB hardware being initialized and the endpoint being correctly configured in the descriptor table.

Uso:
Change this value to true when the host has cleared a stall condition or during error recovery sequences to re-enable communication on a halted endpoint. Do not set this to true prematurely, as it may cause data synchronization errors if the host is not expecting a reset of the data toggle sequence.

`ca_usb_ep_close`

File: `caos/drivers/inc/usb.h`

A configuration flag that determines whether the USB endpoint is automatically closed upon a transmission error or disconnection.

Valore: `(false)`

Note:
When set to true, the system will force the endpoint into a closed state during communication failures, requiring a manual re-initialization. When false, the endpoint remains open, allowing for potential retry attempts without re-configuring the hardware registers. This flag depends on the underlying USB peripheral driver state machine and is typically a boolean value.

Uso:
Set this to true if your application requires strict state management and you want to ensure the endpoint is reset to a clean state after any error. Keep it false if you prefer to handle error recovery at the application layer without re-initializing the USB hardware, which is useful for high-speed data streams where re-initialization latency is unacceptable.

`ca_usb_ep_is_stalled`

File: `caos/drivers/inc/usb.h`

A boolean flag indicating whether a specific USB endpoint is currently in a stalled state.

Valore: `(false)`

Note:
When set to true, the USB controller will respond with a STALL handshake to any host requests on this endpoint, effectively halting data transfer. This flag is typically managed by the USB stack's control transfer logic. It depends on the hardware-specific endpoint status register and should be synchronized with the USB interrupt handler.

Uso:
Change this value to true when the application needs to signal a protocol error or an unsupported request to the USB host. Set it to false to clear the stall condition after the error has been handled. Incorrectly setting this value can cause the USB host to drop the device connection or report a device malfunction.

`ca_usb_ep_open`

File: `caos/drivers/inc/usb.h`

Configures whether the USB endpoint is automatically opened and initialized during the USB stack startup sequence.

Valore: `(false)`

Note:
When set to true, the endpoint is initialized immediately upon USB driver start. When false, the endpoint remains closed until explicitly opened by the application code. This flag depends on the USB peripheral being correctly clocked and configured in the device tree. Typical values are boolean true or false.

Uso:
Change this to false if you need to perform complex hardware initialization or wait for specific application states before the USB endpoint becomes active. Setting this to false prevents premature enumeration or data reception. Warning: If set to false, ensure your application calls the corresponding open function, otherwise, USB communication will fail to initialize.

`ca_usb_ep_read`

File: `caos/drivers/inc/usb.h`

Configures the USB endpoint read mode, determining if data reception is blocking or interrupt-driven.

Valore: `(0)`

Note:
When set to 0, the system uses a polling-based read mechanism. Enabling this (setting to 1) switches to an interrupt-driven buffer management system. This flag depends on the USB peripheral clock being enabled in the system configuration. Valid values are 0 (polling) or 1 (interrupt-driven).

Uso:
Change this to 1 if your application experiences data loss during high-speed USB transfers or if the CPU needs to perform other tasks while waiting for data. Keep it at 0 for simple, low-bandwidth applications to reduce interrupt overhead. Warning: setting this to 1 requires implementing the corresponding interrupt service routine (ISR) in your application code.

`ca_usb_ep_write`

File: `caos/drivers/inc/usb.h`

Configures whether the USB endpoint write operation should be performed in blocking or non-blocking mode.

Valore: `(false)`

Note:
When set to false, the function returns immediately after queuing the data for transmission, preventing the CPU from stalling. If set to true, the function waits until the hardware buffer is ready or the transfer completes. This flag depends on the underlying USB peripheral driver state and should be kept false to maintain high system responsiveness in an RTOS environment.

Uso:
Change this to true only if you are performing synchronous data transfers where the application must guarantee the data has left the buffer before proceeding. Warning: setting this to true in a high-priority task can cause system-wide latency spikes or watchdog timeouts if the USB bus is busy or disconnected.

`ca_usb_get_speed`

File: `caos/drivers/inc/usb.h`

Defines the operational speed mode for the USB peripheral interface.

Valore: `(CA_USB_SPEED_FS)`

Note:
This constant sets the USB controller to Full-Speed (12 Mbps). Disabling or changing this value may cause the USB peripheral to fail enumeration if the hardware or the host controller does not support the selected speed. It is typically dependent on the system clock configuration and the specific USB PHY hardware present on the STM32 chip.

Uso:
Change this value only if the hardware design requires High-Speed (480 Mbps) or Low-Speed (1.5 Mbps) operation. Ensure that the system clock (HCLK) is configured to meet the timing requirements of the selected speed mode, otherwise, the USB stack will fail to initialize or experience frequent data transmission errors.

`ca_usb_init`

File: `caos/drivers/inc/usb.h`

Initializes the USB peripheral hardware and internal driver stack during system startup.

Valore: `(false)`

Note:
When set to true, the RTOS will automatically configure the USB controller, clocks, and GPIO pins during the kernel boot sequence. If set to false, the USB peripheral remains in a low-power reset state, and the developer must manually call the initialization function later in the application code. This flag depends on the hardware abstraction layer (HAL) being correctly configured for the specific STM32 target.

Uso:
Set this to true if your application requires USB connectivity (e.g., CDC, HID, or MSC) immediately upon power-up. Set to false if you need to perform complex pre-initialization tasks, want to save power by delaying USB startup, or if the USB pins are being used for other purposes during the early boot phase. Warning: disabling this without manual initialization will cause USB-related API calls to return errors or trigger hard faults.

`ms_to_ticks`

File: `caos/inc/systick.h`

A macro that converts a time duration in milliseconds into the equivalent number of RTOS system ticks.

Valore: `ca_os_tick_x_ms(ms)`

Note:
This macro relies on the system clock frequency defined by CA_OS_TICK_RATE_HZ. Enabling this allows the scheduler to calculate delays and timeouts based on real-time units rather than raw tick counts. The result is an integer value representing the number of ticks required to span the requested milliseconds. If the requested time is shorter than one tick period, the result may truncate to zero.

Uso:
Use this whenever you need to specify a timeout or delay in milliseconds for RTOS primitives like osDelay() or semaphore timeouts. Change this when you need to adjust the system tick frequency to ensure your timing logic remains consistent. Warning: Ensure that the resulting tick count does not exceed the maximum value allowed by the underlying data type (typically uint32_t) to avoid overflow errors.

`seconds_to_ticks`

File: `caos/inc/systick.h`

A conversion macro that translates a duration in seconds into the equivalent number of system ticks.

Valore: `ca_os_tick_x_ms((s) * 1000)`

Note:
This constant relies on the system tick frequency defined by ca_os_tick_x_ms. Enabling this allows developers to specify timeouts or delays in human-readable seconds rather than raw tick counts. It is mathematically dependent on the OS_TICK_RATE_HZ configuration; if the tick rate changes, this macro automatically scales correctly.

Uso:
Use this when setting task delays, software timer intervals, or timeout parameters in API calls where you prefer to define time in seconds. Change this value only when you need to adjust the granularity of your timing logic. Warning: Ensure the resulting tick count does not exceed the maximum value of the variable type used by the receiving function to prevent integer overflow.

Chapter 118

Call Graph API caOS

Diagrammi delle relazioni di chiamata tra le funzioni caOS, raggruppati per file sorgente che le implementa (le funzioni HW di famiglia stanno col driver generico). Ogni nodo rappresenta una funzione pubblica; le frecce indicano chi chiama chi. Nodi **gialli**: chiamanti dagli esempi. **Verdi**: applicazioni del workspace. **Rosa**: altri moduli caOS. **Grigi**: driver HW (numero di famiglie).
